Lettsomian Lecture

ON THE

JRGERY OF THE SPINAL CORD AND ITS MEMBRANES

ing the Third Lettsomian Lecture in 1927 delivered before the Medical Society of London on March 21st, 1927,*

Y DONALD ARMOUR, C M G, M B TORONTO,
F R C S ENG, M R C P. LOND,
SENIOR SURGEON TO THE WEST LONDON HOSPITAL AND
SURGEON TO THE NATIONAL HOSPITAL FOR
DISEASES OF THE NERVOUS SYSTEM

OF all the ills that human flesh is heir to there none more terrible to bear by the patient by the atives and by the medical attendant himself, than ntinuous pain beyond relief by ordinary therapeutic easures Of such as these are the pain of inoperable alignant disease, especially that of the vertebral lumn and the visceral crises of tabes dorsalis is not to be wondered at therefore that attention s been directed to surgical measures in an attempt find relief for the intractable pain of the one e repeated attacks of pain and vomiting of the other.

SURGICAL MEASURES FOR THE RELIEF OF PAIN.

Dana was the first to propose the division of sterior spinal nerve roots for the relief of severe untic pains and William Bennett was the first to rry out in 1888 the suggested operation He was lowed by Abbe and Munro Horsley Chipault, Mculin and Monod and Giordano all of whom erated for inveterate neu[illegible] and by Faure, in 39, who operated with [illegible] pain in a case of operable carcinoma [illegible] s introduction it s been performed [illegible] ly with varying ccess, chiefly for inveterate neuralgia following upon ury or after amputations, and for the excruciating in in malignant disease of the spine In 1900, ngazzini suggested that the posterior nerve roots ould be cut for the relief of severe lightning pains tabes This suggestion was not acted upon until 08, when at Förster's request, Küttner in a twoge operation cut the seventh, eighth, ninth and nth dorsal posterior nerve roots in a patient ffering from gastric crises with extraordinarily good sults Previous to this date however, Vallas and tte, in 1906, had treated a case of severe gastric ises by stretching the solar plexus, with complete lief for four months

Reference may be here made to intradural and ndural injections of various substances for the lief of gastric crises and lightning pains in tabes ippmann advised the injection of 5 c cm of 1 per nt solution of sodium bromide into the subachnoid space while Hauptmann practised air placement in the spinal subarachnoid space after ithdrawing 90 c cm of cerebro-spinal fluid Both ethods have failed of any result when used at the ational Hospital Lévy, Pope and Brissaud have dvocated the injection of fibrolysin water, alcohol, nd stovaine into the spinal subarachnoid space hile Sicard and Cathelin recommend that the njections should be epidural. Paravertebral injection f alcohol into the splanchnic nerve has also been tried armichael, at the National Hospital, has used an ntravenous injection of hypertonic saline solution 30 c cm of a 30 per cent solution) in a number of ases with immediate good results in the majority of cases No such result was obtained when normal saline solution was used as a control The improvement however, was not permanent, the vomiting remaining unchanged, though it sometimes appeared as if the pain were lessened

SECTION OF THE POSTERIOR ROOTS

Forster's recommendation of posterior spinal root section is based on his conception that the visceral crises are due to an exalted reflex action, and that in order to inhibit this it is necessary to break the nervous arc upon which it depends In his opinion the primary cause of gastric crises is an irritation of the sensory sympathetic fibres from the stomach, which fibres enter the spinal cord through certain of the posterior nerve roots These sensory sympathetic fibres pass to the cœliac plexus then by the rami communicantes to the seventh, eighth, and ninth dorsal posterior spinal roots and from these to the cord It should be remembered however that Forster gave warning that all cases of gastric crises without any pain should be regarded with suspicion and as unsuitable for section of posterior nerve roots He regards these as of vagal origin

Various modifications of Forster's operation have been tried since its introduction Pal recommends on anatomical grounds the section of the rami communicantes. Francke, in a case where root section had been refused obtained complete success by a slow avulsion of the corresponding intercostal nerves After cutting the seventh eighth and ninth intercostal nerves on each side he twisted out the central end until he reached the ganglion and thus destroyed the rami communicantes Dujarrier reports the same result in a case similarly operated on by Maire, of Vichy Guleke and Lamprecht advise extradural root section, while Von Franke-Hochwart contented himself with intercostal nerve section alone, which was quite unsuccessful Bierens de Haan in 1920, reported a case in which transient paralysis with retention of urine and fæces and trophic troubles, followed upon posterior root section for gastric crises

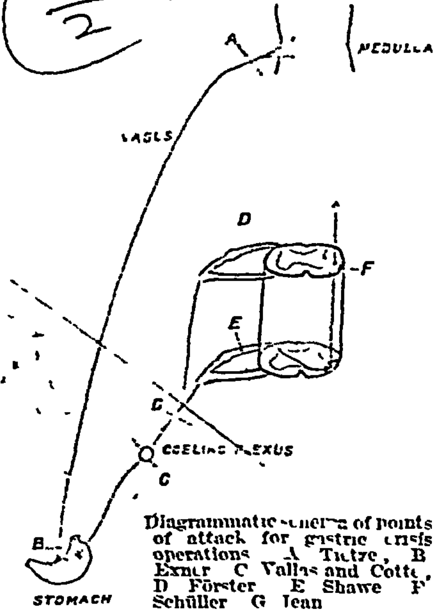
FIG 1



Diagrammatic scheme of points of attack for gastric crisis operations A Tietze, B Exner C Vallas and Cotte, D Förster E Shawe F Schüller G Jean

In spite of the many brilliant results reported from root section, Forster in 1910 turned his attention elsewhere and persuaded Tietze to cut the sensory roots of the vagus at their medullary origin, but the result was fatal In 1911, Exner divided both vagi in two patients following it with a gastro-enterostomy to overcome the paralysis of the stomach but the operation was ineffective Cotte resected the gastric branches of the vagi in three cases all of which w [illegible] failures (Fig 1.) Thomsen in 1924 repeated [illegible] operation, with a success of one year's duration [illegible] 1921 on theoretical grounds advocated eith [illegible] of the thoracic ganglia or cutting the gr [illegible] nerve He performed the operation [illegible] consequently extrapleural route on dogs and [illegible] ormal position of never put it into actual pra [illegible] cess been fractured Wolfsohn report five cases of [illegible] ld be effected but with in only one of which was th [illegible]

The objective and su [illegible] then, the cases collected persisting after poster [illegible] and in 1918 by Prof Schenk a good deal of spec [illegible] that patients with anterior been made to explain them The frequent reappearance of the pain, even after the most extensive root section, has led Critchley to ask whether the intensity of the pain stimulus produces an overflow into other conduction paths Leonard Kidd, in 1911, concluded that afferent fibres exist in the spinal ventral roots of man Lehmann, in 1920, from the results of posterior root section in dogs came to the conclusion that pain sensations probably travelled via the anterior roots Shawe, in 1924, basing his conclusions upon a large amount of original work conducted along clinical and experimental lines, thinks the operative treatment of gastric crises should comprise section of both anterior and posterior nerve roots

---

* The first and second Lettsomian Lectures appeared in THE LANCET of Feb 26th and March 12th respectively

This has been put to the test at the National Hospital by my colleague Sargent in two cases In one he cut the fifth to the eighth posterior roots on both sides, and the fifth and seventh anterior roots on the left side, and the fifth, sixth, and seventh anterior roots on the right side In the other case he cut the seventh, eighth, ninth, tenth, and eleventh anterior and posterior roots on the right side only In the first case the attacks of pain and vomiting returned within a few weeks of the operation and persisted unchanged for a year There was no alteration in the nature or severity of the crises Then they ceased for a year and a half, after which intense pain reappeared but with no associated vomiting In the second case pain and vomiting persisted, although the character of the pain was somewhat modified after the operation

So popular had posterior rhizotomy become that Hey Groves, in 1911, summed up the current opinion of the procedure as follows: "For the relief of visceral crises the operation holds out the only prospect of radical cure which we know at present"

That "present" was to be of short duration In 1917 Frazier stated that of all cases reported as operated on by posterior root section, only 19 per cent could be claimed as cures, while the operation mortality stood at 15 7 per cent Leriche, in 1922, went still further and stated that he had never seen tabetic crises disappear even after the most extensive posterior root section, a section in some cases extending to seven or eight roots on each side

Apart from the possible failure of posterior rhizotomy for the cure of pain and its probable uselessness in gastric crises, there are two serious disadvantages, one surgical and the other functional, attached to the operation Owing to the wide overlapping of sensory nerves and the usually wide area of pain, the division of several consecutive roots probably on both sides is required This necessitates an extensive laminectomy, often upon a bad operative risk. While loss of pain and temperature sense is no inconvenience, yet the loss of sensations of touch, motion, and position is a very definite handicap To overcome this it has been suggested that every third root be left But such a manœuvre will result in the pain not being completely abolished

Partial Division of the Spinal Cord

It was owing to the equivocal reports upon the results of the operation of posterior root section, results which showed a rapidly increasing percentage of failures, that led Schüller, in 1910, to suggest that a partial division of the spinal cord might be employed instead of root section in gastric crises and spasticity He thought that the posterior columns might be cut for spasticity, either alone or with the direct cerebellar [illegible]ct, and that the anterolateral tract might be cut [illegible]astric crises

[illegible] 1910 Cushing had suggested "the deliberate [illegible]n, either of the entire cord or of the posterior [illegible]e, cephalad to the lesion" for intractable [illegible]g pain from malignant spinal meta- [illegible]rmed such an operation in 1916, [illegible] the thoracic region with an [illegible] result Previous to Cushing's [illegible]d the same procedure in [illegible] [illegible]ceived a shrapnel wound [illegible]tomy at the level of the twelfth dorsal and first and second lumbar vertebræ had been performed, shrapnel removed, and the cauda equina sutured. He was admitted to the National Hospital under the care of Risien Russell, with a complete flaccid paralysis of the lower limbs, with marked muscular wasting, and retention of urine and fæces. He suffered from intense pain in the lower limbs, especially in the upper part of the thighs, and in the lower part of the abdomen

At operation the cauda equina and lower end of the spinal cord were found enveloped in a mass of scar tissue I did a transection of the whole cord immediately above the lesion, and cutting through the roots below removed the lower end of the cord. There was complete loss of pain, he was able to do without morphia, and left the hospital much improved

Section of the Anterolateral Column

In 1911 Spiller as a result of his observations on a case to be referred to later, was led to propose section of the anterolateral column for intractable pain in a case of malignant growth in the spinal cord The operation was performed by Martin on Jan 19th, 1911, both anterolateral tracts being divided to a depth of about 2 mm at a point opposite the seventh dorsal vertebra Pain was much diminished and a year later Spiller regarded the result as successful

At Spiller's suggestion, Cadwalader and Sweet undertook some experiments on dogs to show the effects of cutting the anterolateral tract In their cases, motor paralysis was noted immediately following the operation, but it disappeared very rapidly and was replaced by marked ataxia As microscopically no injury was found in the pyramidal tract and von Monakow's bundle, they assumed the transient paralysis to be due to a temporary vascular disturbance

The second occasion on which section of the anterolateral tract was performed was in 1912 by Beer for the relief of pain due to metastases from uterine carcinoma The operation was done at the level of the tenth dorsal vertebra and gave complete analgesia and loss [illegible] cold perception on the rig[illegible] side up to the le[illegible] pubes The pain in the back, however, wa[illegible] Later, the operatio was performed by [illegible] the suggestion of Forste and in 1920 Frazier reported six cases upon which h had operated, all for pain due [illegible] malignant disease [illegible] following gunshot wounds

Souttar was the first to do an anterolateral section for gastric crises in tabes He operated on a patient of Sydney Owen's at the West London Hospit in 1915 It was a unilateral section on the rig side between the first and second dorsal segment The result was immediate relief of symptoms, whic relief had persisted for ten years Since the operations, either unilateral or bilateral, have bee reported by Leighton, Sachs, Grant, Nonne, an Tietze for the gastric crises of tabes, and by Pee Sicard and Robinson, and Frazier for intractab pain due in most cases to inoperable malign disease The results, especially in the latter type case, have been on the whole very successful

On what anatomical grounds is the operation anterolateral tract section based ?

ANATOMY.

The ascending or centripetal tracts have their ce of origin in the posterior root or spinal ganglia The cells are connected peripherally by means of fibr running in the nerve trunks with the various peripher organs found in the skin, mucous membran mesentery, articular surfaces, muscles, and elsewher Centrally the fibres from the cells of the posteri root ganglia pass by way of the posterior roots in the spinal cord In the cord their further course ma be a short, medium, or long one The short fibr pass directly through the marginal zone of the posteri horn into the grey matter, when they end arborising among the cells of the posterior and anteri horns of the same side of the cord The mediu fibres pass through the segment of entry into t posterior columns and from thence into the dors horn of the same side, ending in Clarke's colum The long fibres pass through the segment of ent into the posterior columns and passing upwar terminate in the nuclei of the dorsal columns in the medulla

The endogenous tracts of the spinal cord include the centripetal fibres of the second order and the so-called intersegmental tracts The latter serve to connect the grey matter of successive segments of the cord Under the former are included those fibres which provide for the further conduction towards the sensorium of impulses received through the elements of the posterior roots which have already terminated in the cord They include the dorsal spinocerebellar or direct cerebellar tract, the ventral spinocerebellar, anterolateral ascending or Gowers' tract, and the spinothalamic tract These, together with the crossed pyramidal tract and lateral ground bundle constitute the lateral column of the cord Their relative position is as follows. (Fig 2) in the hinder part of the lateral column, occupying a somewhat triangular area, is the crossed pyramidal tract External to this and occupying a narrow area at the periphery of the cord which extends backwards to the postero-lateral fissure is the direct cerebellar tract Gowers' tract, an extensive crescent-shaped strand occupies the anterior three-quarters of the periphery of the lateral column Behind, where it is thickest, it lies in the angle formed by the direct cerebellar and crossed pyramidal tracts becoming thinner as it passes forwards The spinothalamic tract is situated opposite the base of the posterior horn and lies in close apposition to the inner side of Gowers' tract (Fig 3) It is a crossed sensory tract, whose fibres are the axons which arise from certain cells in the posterior horn, and crossing to the opposite side of the cord through the anterior commissure ascend in the anterolateral column, finally reaching the optic thalamus They are not gathered into a compact bundle but are more or less loosely scattered in the lateral column The rest of the lateral column of the spinal cord is occupied by the lateral basis or ground bundle It surrounds the anterior horn and separates the aforementioned tracts from the grey matter of the cord It consists of (1) longitudinal commissural fibres, which unite the groups of cells in the grey matter with one another, (2) fibres which pass across the anterior commissure from the grey matter of the opposite side, and (3) horizontal fibres belonging to the anterior roots of the nerves which pass through it before leaving the cord

FIG 2

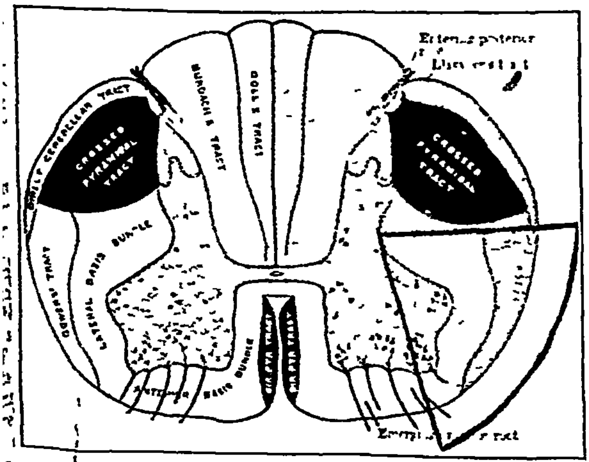


Diagram showing relative positions of tracts in the spinal cord and area involved in anterolateral section (Cunningham's anatomy)

THE SENSORY APPARATUS OF THE SPINAL CORD

In order to reach the sensorium, sensory impulses, originating in the trunk or limbs, make their way into the spinal cord through the spinal ganglia and the posterior nerve roots These impulses have to do with tactile sensibility, sensibility to pain, temperature sense, and deep sensibility The fibres which serve for the conduction of sensory impressions of the above four categories separate from each other immediately after entering the cord Or, in other words, each one of the specific impulses, such as pain, touch, heat, and cold, has its own tract in the spinal cord devoted to its conduction Brown-Séquard, about 75 years ago, stated that division of one half of the spinal cord caused loss of sensibility to pain on the side opposed to the lesion, and that motion was affected on the same side Though his statement has been attacked from time to time, both by clinicians and experimental physiologists, nevertheless the close relation between the impulses for sensations of pain and temperature has long been universally recognised. So that whatever may happen to the impulses which underlie other forms of sensibility, there can be little doubt that in man those for pain, heat, and cold cross to pass up the opposite side of the spinal cord But, as Head and Thompson point out, although the impulses for pain, heat, and cold are so closely associated in their passage up the spinal cord on the side opposed to their point of entry, they do not travel inextricably intermingled Moreover, and this is of outstanding importance in connexion with our subject, they found that when sensibility to pain is abolished from an intramedullary lesion no normally painful stimulus will produce a painful afferent impulse The question of the conduction of tactile stimuli would appear to be still sub judice. Mann supposes that tactile impulses pass up any open centripetal path, and that so long as fibres are present for the transmission of centripetal stimuli, these can be followed by the tactile sensations, even although the posterior columns mainly subserve this function Pétren, Borchert, Rothmann, Bing, and others also assume a crossed and an uncrossed tract for the transmission of tactile sensations

FIG 3

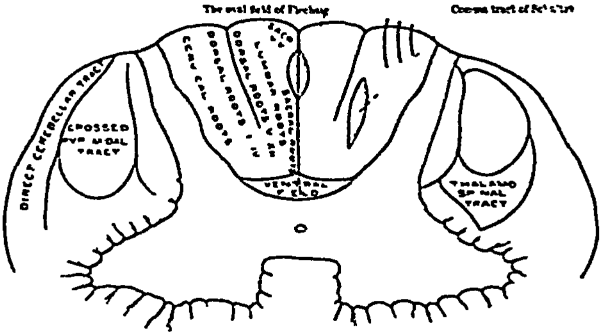

Diagram showing position of spinothalamic tract (Cunningham's anatomy)

Head and Thompson sum up their conclusions as follows.—

> "Tactile, painful, and thermal impulses, and those associated with tactile localisation, cross in their passage through the spinal cord, and show evidence of recombination. But the sensory impulses which underlie the recognition of passive position and movement and tactile discrimination do not cross within the limits of the spinal cord."

They think, however, that for tactile impulses the
crossing is less rapid than for the others And u[illegible]
this crossing is finally completed, that two path[illegible]
be open for tactile impulses one in the primary[illegible]
of the posterior columns, the other in th[illegible]
intramedullary system, in which [illegible] by both
recombined into a specific [illegible] extent Spi[illegible] consequently
forms of tactile sensibil[illegible]eral section o[illegible]ormal position of

Conduction [illegible]ility is lost [illegible]ocess been fractured

At present. howe[illegible]rolateral ch[illegible]ild be effected but with

Are fibres for pain co[illegible] of [illegible]and in 1918 by Prof Schenk
spinal cord, and if so [illegible] that patients with anterior

by ablation of this system? And can pain sensations be conveyed by other systems when the fibres usually employed for this purpose are destroyed?

Head and Holmes put the matter clearly as follows:—

"Within the spinal cord all impulses capable of generating pain become grouped together in the same path and can be disturbed simultaneously by an appropriate lesion of the spinal cord In the same way sensibility to heat or cold may be lost independently of one another, showing that all the impulses on which they are based have been sorted out into two functional groups, each of which passes by a separate system in the spinal cord It should be possible, therefore, to divide the tracts for the conduction of pain with little damage to the rest of the cord, except that the fibres for temperature would probably be implicated It is questionable whether objective disturbance of sensation would be produced by such an operation, and if so, whether it would be persistent"

FIG 4

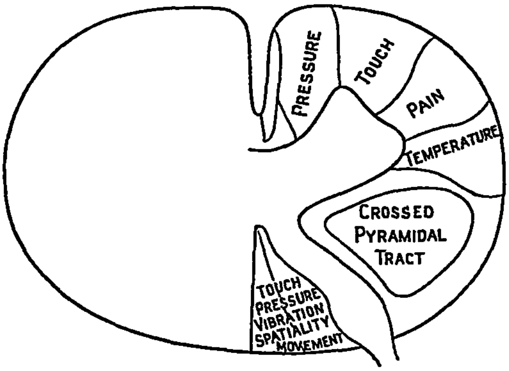

Diagram showing Förster's provisional arrangement of sensory tracts in the spinal cord

How rapidly does the crossing of the fibres conveying painful impulses take place in the spinal cord? Head and Thompson think that the impulses produced by painful pressure from the same part of the body do not enter the cord by the same posterior roots as those carrying the impulses produced by cutaneous painful stimuli Therefore that more than one segment of the cord is required before all the painful impulses from any one part of the body can be gathered together and recombined Piltz thinks that impulses associated with pain, heat, and cold seem to pass completely to he opposite side in the space of five or six segments pinions, however, differ as to how many segments are involved in the crossing, though most observers consider that two, three, or even five segments are necessary

Forster in his work published this year says as a result of his investigations, that "the crossing does not take place in the horizontal plane, but in a steeply ascending direction The fibres coming from one segment of the posterior horn cross in the territory of the segment immediately above, and the crossing is completed by the upper end of this latter segment" For instance, he found that after section of the anterolateral tract at the upper end of the third dorsal segment, there resulted a total analgesia and therm-anæsthesia in the fourth dorsal dermatome, and that after section at the upper end of the sixth cervical segment anæsthesia and analgesia were complete in segments up to the seventh cervical And that bilateral section of the anterolateral tract at per end of the fifth thoracic segment all the mes from the sixth dorsal to the third sacral c and therm-anæsthetic In these three n, crossing was complete within the e, ceph

g pain fro eral rule, there is no med such sensation except the teral columns In result res conveying pain d th up the cord in the 1893 van Gehuchten 904 Spiller was able to give clinical proof of the correctness of these opinions in a patient with complete loss of sensation for pain and temperature in the lower limbs, with preservation of tactile sensibility At his death in 1905, necropsy revealed a solitary tubercle involving the right Gowers' tract at the lower end of the thoracic cord, and slightly above this another solitary tubercle implicating the left tract of Gowers Forster records a personal experience in which, while giving an injection of novocaine for intercostal neuralgia, the needle passed through an intervertebral foramen and the dura and impinged upon the cord The patient at once complained of terrible pain in the leg of the opposite side He says that he has frequently observed that pricks, cuts, or light touches on the anterolateral tract of the exposed cord causes severe pain in the opposite leg, while similar manipulations of the posterior columns were completely free from any reaction Spiller, Taylor, Greenfield, and Martin have described cases of syringomyelia in which the severe pain can only have been due to an irritation of the lateral tract

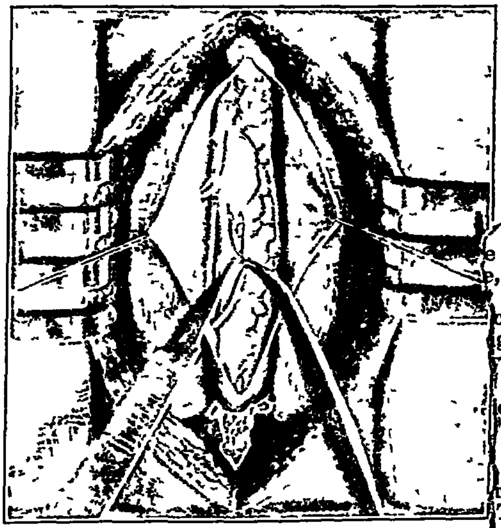
Localisation in the Anterolateral Column

Knowing that afferent impulses pass up in the anterolateral column, and further, that each specific impulse has a specific tract devoted to its conduction, is there any evidence as to the position which each occupies, both in the column itself and in relation to each other On these points Forster says —

"If we must assume a separate region for the paths of pain in the anterolateral column, we, however, do not know exactly, so far, which special area contains the pain and which the temperature sensation I provisionally place the temperature paths in the dorsal part of the anterolateral tract, and the pain paths immediately in front of them" (Fig 4)

Are there other paths, in addition to the long centripetal paths in the posterior and anterolateral columns, by which afferent impulses can p Karplus and Kreidl, as a result of their resear along the lines formerly taken by Schiff, think there is another possible path for the conductio pain—viz, the grey matter On this point Fo says —

FIG 5

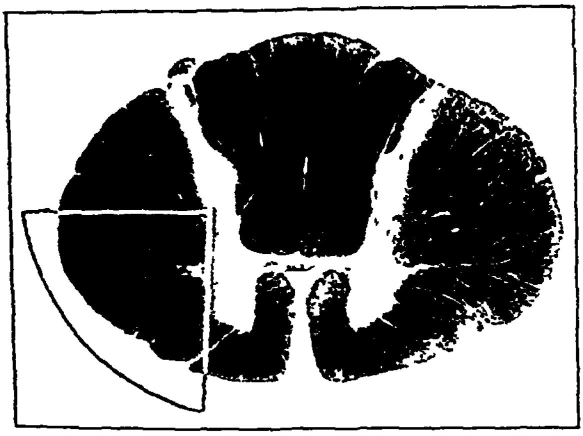


Anterolateral tract section Cord rotated by forceps gras cut end of dentate ligament (Peet)

"The posterior horn columns on both sides obviously numerous short chains of neurons, which, put together, a continuous path, which can carry up pain impulses to the brain on their own side without taking any part i long ascending tracts, and thus stimuli, which affect side, can be transmitted by the opposite side of the post horn columns" He goes on to say that, "these funicular for pain through the grey matter are natu only by-passes"

This would explain those cases in which pain perception has remained after bilateral section of the anterolateral tracts Frazier thought that in his cases this was due to some of the pain-fibres in the anterolateral tract escaping the knife Forster on the contrary, thinks that we must assume that the integrity of pain sensation, in spite of cutting of the anterolateral tract in certain individuals, is due to the existence of a by-pass He is in doubt as to whether this is to be looked for in the posterior columns or whether we are to assume a posterior horn path But on the whole, as a result of the experiments of Schiff, Rothmann, Karplus, Kreidl, and others, he thinks that only the path in the posterior horns can be assumed

FIG 6.



Transverse section of the spinal cord at level of the second dorsal segment showing area involved in anterolateral section

SECTION OF THE ANTEROLATERAL TRACT

The operation of anterolateral tract section should offer no special difficulties to the surgeon trained in neurological surgery. Exposure of the cord of sufficient extent can be obtained by the removal of two, or at the most three, laminal arches The dura s opened in the entire length of the wound The arachnoid is also freely and carefully opened, so as o expose the exact attachment of the ligamentum enticulatum and the emerging anterior root One the denticulations of the ligament is cut at its achment to the inner surface of the dura, and its t end seized with fine forceps By steady and gentle iction on it the cord is carefully rotated to expose anterolateral surface (Fig 5)

The success or failure of the operation depends tirely upon the accuracy with which it is performed requires of the operator an accurate knowledge of microscopical anatomy of the spinal cord and an ility to visualise such anatomy on the surface osed to view. The chief danger is damage to the ssed pyramidal tract (Fig 2) The section concerns y that part of the lateral column which lies anterior point midway between the posterior and anterior ts, and commences just anterior to the reflection the dentate ligament from the cord The knife uld be carried forward parallel to the antero-terior axis of the cord and made to emerge through t the median side of the anterior root (Fig 6) depth of the incision should be not less than mm nor more than 3 mm It may be made with ery fine-pointed sharp knife, marked so that a th of 3 mm can be accurately determined ittle or no bleeding results from the incision upulations should be of the gentlest kind and no sure exerted on the cord during them The use suction apparatus does away with the necessity ponging and facilitates the performance of the t delicate stage of the operation Should a eral section be indicated, exactly the same procedure is carried out on the opposite side of the cord The dura is closed by a continuous suture of fine catgut and the muscle layers by interrupted sutures in the usual way The postoperative treatment is the same as after laminectomy for any other condition, but the nursing is facilitated by the more restricted area of bone removal allowing of freer movement of the patient The bladder and rectum are almost invariably unaffected and trophic disturbances should not occur

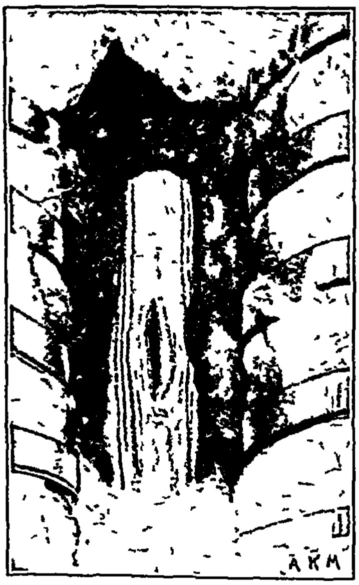
The level selected to do a section of the anterolateral tract will depend first upon the segmental areas involved in the pain-producing lesion, and, secondly, upon the number of segments necessary for the complete crossing of all the fibres from those areas Peet says it is essential that the division should be at least four segments above the area to be rendered analgesic But in cases of upper abdominal pain he also cuts the posterior nerve roots in the exposed field, adding, he thinks, another segment to the analgesic area But surely this is "making sure doubly sure ' with a vengeance Frazier takes a level at least four segments above the area of the lesion and adds two or three segments to that, to allow for a possible extension upwards of the pain-producing lesion

If we are to accept Forster's conclusions published a few weeks ago and already referred to—viz , "that all the fibres coming from one segment of the posterior horn cross in the territory of the segment immediately above and the crossing is completed by the upper end of this latter segment," it will not be necessary to go so far afield in segmental levels as has been done in the past

A NEW OPERATION

Dr. Godwin Greenfield of the National Hospital, has suggested a new method of performing chordotomy. The operation consists of a mediolongitudinal section of the cord at the selected level and is applicable to the same class of case as the anterolateral tract section (Fig 7) It has the advantage over the latter that a bilateral effect is obtained by one incision, which completely destroys *all* the pain-conducting fibres crossing at the level of incision In pain arising from internal organs, whether due to malignant disease or in gastric crises no relief is ever obtained from unilateral chordotomy a bilateral section being always necessary

FIG 7.



Operation of mediolongitudinal section.

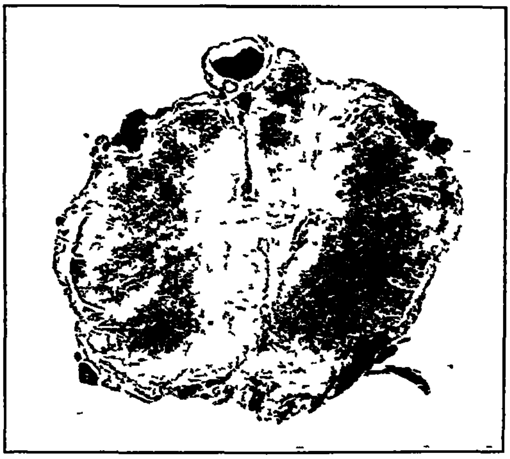
longitudinal section h that patients with anterior

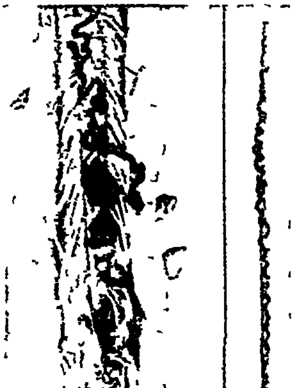
there is no risk of injury to the crossed pyramidal tracts with resulting motor weakness or paralysis, and the long centripetal tracts are untouched This operation has its special application in painful lesions of the lower limbs and pelvic organs A mediolongitudinal incision, of about one inch in length, at the level of the eleventh and twelfth dorsal and first lumbar segments, would destroy all pain-fibres coming from the lower limbs and pelvis Higher up in the cord the length of the incision would obviously have to correspond to the segmental distribution of the pain Two points in technique are of importance The incision must be made exactly in the midline of the cord, and the anterior spinal artery, which lies at the surface of the anterior median fissure, must be avoided The exposure of the spinal cord is carried out in the same way as in laminectomy for other conditions, and its length will be governed by the length of the incision to be made in the cord

FIG 8



Transverse section of the spinal cord showing result of mediolongitudinal section

FIG 9



giectasis of posterior spinal with (inset) enlarged and vessel on nerve root

I performed this operation before the inaugural meeting of the Association of British Neurological Surgeons in December, 1926, on a patient suffering from gastric crises in a very severe form The operation presented no inherent difficulties, and the danger of damaging the anterior spinal artery was obviated by the use of a knife in the last stage of the section, by he pia-arachnoid together with the forward and out of danger (Fig 8) tient, who was a poor operative ng, died of pneumonia a few Perhaps, too, the occasion performance of such an on But of its feasibility and its usefulness in properly selected cases I think there can be no question It is a testimony, too, to the broad vision of the distinguished neuropathologist who first conceived it

TELANGIECTASIS OF THE SPINAL CORD AND MEMBRANES

The condition to which I desire to call attention in the latter part of this lecture has been described under various names by different authors, though none of them venture upon an explanation of its pathogeny Telangiectasis, angioma, hæmangioma, cavernous angioma, tumor cavernosus, angioma racemosum (arteriale or venosum), varicocele of the spinal cord, are the various designations under which it has appeared

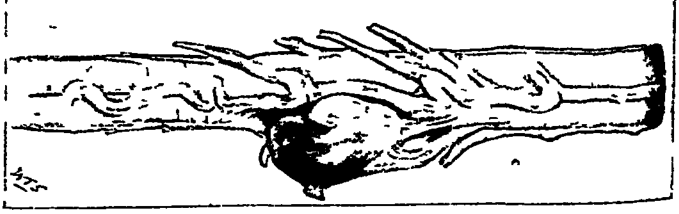
Sir Bernard Spilsbury exhibited a specimen of one of these conditions before this Society in January, 1921 I say " one of these conditions " advisedly, because they do not all show the same characteristics The vessels of the pia seem to be involved in all cases, either alone or in association with an extradural or intra medullary extension In Jumentié and Levy-Valensi's case (Fig 9) the veins of the spinal canal were also involved, the enlarged veins running out through the intervertebral foramina, whilst in Sargent's case of " arterial angioma," the vertebral and spinal muscles were " permeated by numerous dilated, tortuous, thin-walled arteries," which extended into the spinal canal, while at the level of the seventh cervical segment there was a pial aneurysm containing recent blood-clot (Fig 10) In neither of these cases were the intramedullary vessels affected In Raymond and Cestan's case (Figs 11 and 12) the intramedullary vessels, especially of the lower cervical region, were dilated to the same extent as the extramedullary, and showed sac-like dilatations, but the condition did not extend extradurally Whilst in the case reported by Berenbruch, a large cavernous plexus of veins along the spinal column was connected by way of the intervertebral foramina with an angioma of the dura, and an angioma occupied the cord substance from the fifth cervical to the third dorsal segment.

Pathology of the Conditions

Is the underlying pathology of these cases the same, and are they simply different stages in the development of the same primary condition ? Or have we to do with several different conditions ?

Virchow was the first to clearly differentiate between telangiectasis and true angioma He called attention to a point which Adami emphasised—namely, that telangiectasis is a congenital dilatation of capillaries without any new-formed blood-vessels, while an angioma is a new growth, and is only properly so-called where there is a formation of new blood-vessels In the majority of the reported cases no mention is made as to whether arteries or veins, or both, were involved in the process, but it would appear that of those in which it was limited to the pia the veins alone were concerned

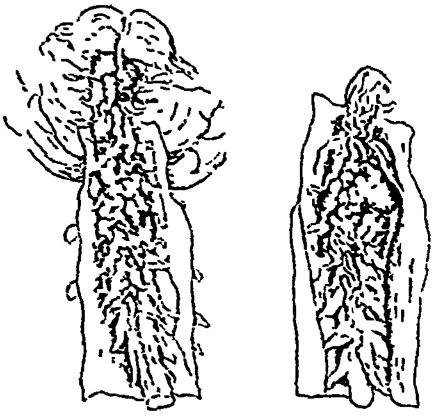
FIG 10



Sargent's case of pial aneurysm

Three theories have been advanced to explain the condition (1) that it is a congenital po anomaly, (2) that it is of neoplastic origin; (3) th these are that it is due to a peripheral constriction with consequent secondary varicosity Against the theo congenital origin t may be remarked that all reported cases except that f Cobb—in which the patient was 8 years old—ave been in adults Virchow maintained that the ondition never occurs in children and was always

FIG 11



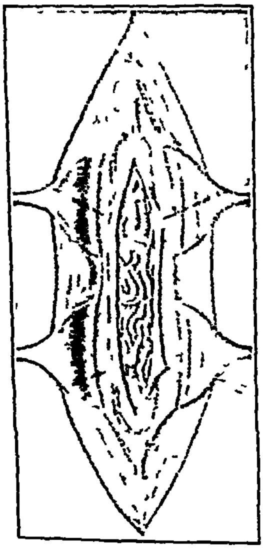
Anterior and posterior surfaces of spinal cord showing dilated vessels

cquired, but that a pre-existing dysplasia may be the rimary cause of the neoplasm

It is difficult to understand how a peripheral onstriction could operate, seeing that the main urrent of venous blood in the spinal cord would ppear to be horizontal in direction, by way of the veins running out along the nerve roots; thus each segment is, as it were, drained by a ring-like arrangement formed by the transverse branches between he longitudinal veins and the offsets proceeding from the latter to the intervertebral foramina

In most of the cases the vessels on the posterior aspect of the cord would seem alone to have been affected, and the most frequently occurring levels are the cervical and lumbosacral regions This may be explained possibly by the fact that the spinal veins are larger on the posterior surface and at the lower end of the spinal cord than elsewhere, and further, that the posterior mediolongitudinal vein is largest and most constant in the cervical and lumbosacral regions of the cord

FIG 13

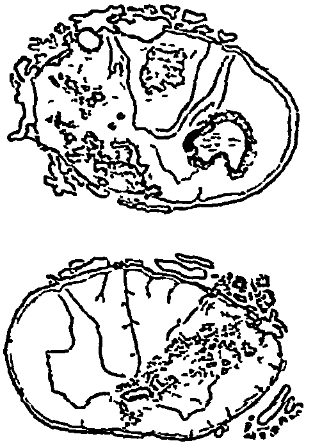


Showing condition usually found on operation for telangiectasis of the spinal cord (Cobb)

In some cases trauma or increased exertion have been adduced as a causative factor Whether the actual cause, or merely causing increased and rapid growth in a pre-existing condition, it is difficult to say Pilzer thinks the process begins primarily as a hæmorrhage, followed by the formation of new vessels with their subsequent dilatation Rolleston has raised the question as to whether the dilated vessels were primary rather than secondary, and due to some morbid change in the inal cord

Some of the cases have been associated with n of the skin Therefore every case of cutaneous us, especially with a segmental distribution, ld be carefully investigated with a view to ng any possible involvement of the cerebrospinal nervous system Such a course might very well show that this condition in the spinal cord is not so rare as is generally supposed A similar cerebral syndrome is already widely recognised

FIG 12.



Showing involvement of the intramedullary vessels in telangiectasis of the spinal cord

Diagnosis and Treatment

In diagnosis the clinical history, as Sargent points out, may be of the greatest value One of the most striking features is the variation in symptoms from time to time The onset is usually sudden, with rapid development, and the symptomatology is that of hæmorrhage into the spinal cord or canal. Then in many cases, recovery, complete or partial, follows, with an interval of days, months, or even years before the next attack Is it not possible that cases may occur with the cause of an attack undiagnosed, followed by recovery, and no further attacks? Sargent's cases are the only ones in which any record of an examination of the cerebro-spinal fluid occurs, and this was done in three cases Two showed xanthochromia and all three an increased protein content The condition is usually revealed as a result of an exploratory laminectomy

If confined to the pial vessels the question may arise of the value of ligation One is then between the Scylla of doing too little and the Charybdis of doing too much As a rule, however, the vessels are enormously distended, with extremely thin and friable walls, closely packed together in an inseparable mass (Fig 13) They form indeed, a veritable noli me tangere, and are better left alone By leaving the dura unsutured one may hope for relief through the decompressive nature of the operation But if the symptoms are due in chief part to circulatory changes in the cord, even this hope will prove elusive.

In concluding this my third and last Lettsomian lecture, I desire to acknowledge the great debt I owe in their preparation to Dr Godwin Greenfield, Pathologist to the National Hospital, to Dr. Arnold Carmichael sometime Medical Registrar there, and to Dr Macdonald Critchley, the present holder of that office

ANTERIOR SUBLUXATION OF THE ATLAS

CAN THE CONDITION BE TREATED BY OPERATION?

By Prof W A OPPEL, Hon F R C S Eng,
LENINGRAD

The sight of a patient with an anterior subluxation of the atlas arouses a feeling of apprehension The head is slightly shifted forwards, the patient carries his head as carefully as though it were made of glass and might at any moment be smashed This helplessness of the head, causing it to be held by the hands of the patient as if to prevent it from falling, at once arouses attention, and has been noted in the recorded cases

General Observations.

We know what is frequently the sequel of an anterior dislocation or subluxation of the atlas; even in the case of subluxation when the anterior arch of the atlas is moved forward the ligamentum cruciatum becomes strained In the case of fracture of the dens (odontoid process) the latter with the anterior arch is also displaced in a forward direction, if the dens remains intact it exerts a pressure on the ligamentum cruciatum displaced forwards And yet behind this ligament, as everybody knows, lies the medulla oblongata.

In case of anterior subluxation of the atlas with the ligamentum cruciatum remaining intact the space allotted to the medulla may be slightly restricted And such a diminution the medulla is capable of enduring But if the atlas be moved ever so slightly forwards and the ligament, unable to bear the strain, is ruptured, the medulla will be instantly compressed And what surgeon does not know that the history of anterior dislocations and subluxations of the atlas is one of sudden death caused by trauma? The number of patients who have not succumbed to such a lesion may be counted on the fingers

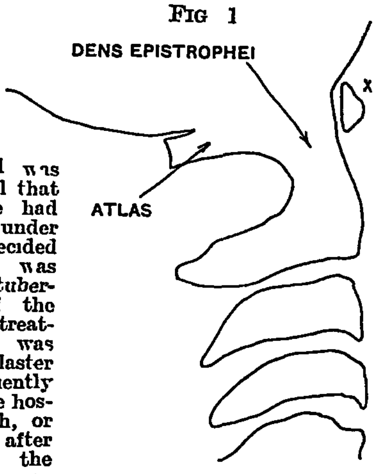
Hence the sight of a patient subject to an anterior subluxation of the atlas causes a most painful ı pression, the head is expected to slip forward at ıy moment and fall over, causing instantaneous death And as a matter of fact such patients live on the brink of death and unfortunately are sometimes reduced to a most helpless condition

Narrative of a Case

On August 5th, 1926, a workman, 30 years old, was admitted as patient into the surgical department of the Mechnikov Hospital, Leningrad The patient was a carrier of heavy weights

On Jan 29th, 1925, the patient was carrying a weight of 200 lb up a staircase to the fifth floor The weight was carried on his back, and the top of the basket, in which it was stowed, projected above his head While carrying the weight the patient observed that something had crunched in the inside of his neck without causing pain Nevertheless, he executed his job and worked on for a couple of hours longer At the expiration of that time, however, he experienced violent pains in the neck, and being unable to move his head was taken into a hospital that evening After he had been placed there under observation it was decided that the patient was *suffering from a tuberculous* affection of the cervical vertebræ A treatment of extension was carried out, and a plaster bandage was subsequently applied He left the hospital on April 24th, or nearly three months after his admission, in the plaster bandage He was treated as an out-patient at the hospital till May 1st, when he resumed his customary work

FIG 1



The radiogram corresponding to this diagram has been abandoned × = The fragment of the arcus anterior atlantis.

At that time the movements of the head became freer and the pains considerably subsided He continued working as a carrier, although he was given lighter weights to carry Occasionally he varied his occupation by working as a clerk During this interval sometimes the movements of the head became all of a sudden difficult and painful, such relapses generally lasted for a day or two, and then the mobility of the head was restored All through this period, however, he had to be careful in moving his head In February of 1926 his head was worse and he was treated at a dispensary as out-patient, when a strain of the cervical muscles was diagnosed After a week's treatment he resumed his customary work

On July 27th, 1926, as he was raising a carcass from the floor, he experienced violent pains in his neck in which

something seemed to have turned On the morning of the following day (28th) he was unable to move his head At the dispensary the same conclusion—i e, strain of the cervical muscles—was reached, and on August 4th he was told that as he had nothing the matter with him he could resume his ordinary work The patient, however, being dissatisfied with such a decision, was examined by a commission, who gave orders to have him admitted to the Mechnikov Hospital

FIG 2 A

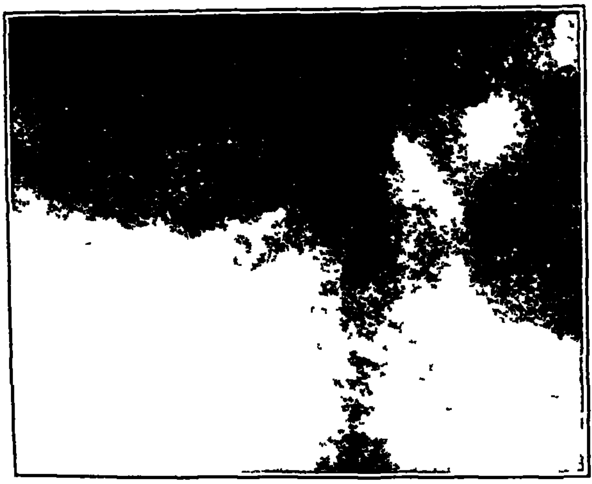

FIG 2 B

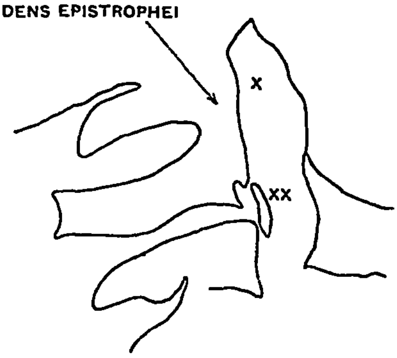


× = Place of the resection The fragment of the arcus anterior is absent ×× = The fragment of the corpus epistrophei

Condition on Admission —The patient is above the middle height, strongly built Holds the head slightly inclined to the right, turns the head with difficulty by a series of jerks The head cannot be inclined forwards, backwards, or to the sides, rotation extremely painful Pains in the region of the right scapula The movements of the upper and lower limbs are free

On examination in profile, the head seems to be slightly displaced forwards, in walking remains quite fixed The patient appears to be taking extreme care of his head for fear of its falling forward. On examination of the pharynx with the fingers the projecting arch of the atlas can be easily perceived It is painful to palpation A Rontgen plate taken of the profile showed (Fig 1) (*a*) the space between the spinous process of the epistropheus (axis) and the posterior arch of the atlas which seems to be increased, (*b*) the anterior arch of the atlas displaced forwards The plate clearly shows that the anterior arch of the atlas is broken off The dens of the epistropheus is so imperfectly seen that it is impossible to decide whether it is fractured or not As the head was fixed, the radiographer was unable to take a picture through the mouth.

The patient sleeps poorly, he is troubled with pains in the neck and cannot lay down his head in a comfortable position Extension and plaster bandages were applied without effecting any improvement.

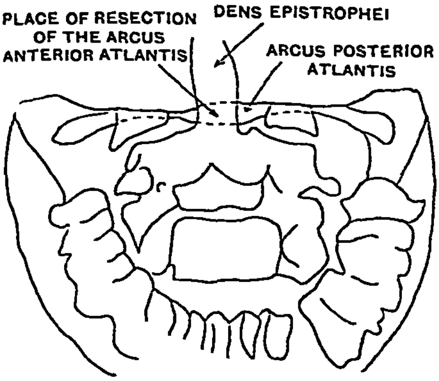
FIG 3 A

Commentary

We were thus confronted with a patient who, a year previously, had experienced a fracture in the cervical region of the vertebral column, presumably in that very part of the region that had been determined by us He had long been under treatment, not been completely cured, experienced an acute relapse of his original injury, and then entered the surgical department of the Mechnikov Hospital It is to be noted that patients suffering from subluxation of the atlas survive this injury and sometimes seem all but restored to health, when some awkward movement of the head occasions sudden death, due to a further slipping forward of the atlas Such is the evidence of literature The patient in question had also obtained relief under a long period of treatment, resumed his work, during which he had a relapse, which luckily for him had not ended in death

The complex of symptoms, including the evidence of the rontgenograms, was in this case perfectly clear The patient was suffering from an anterior subluxation of the atlas with a fracture of the anterior arch The rontgenograms, however, could give no exact information as to one point, whether the dens of the epistropheus was fractured or not Anterior dislocations and subluxations of the atlas are more frequently than not accompanied with separation of the process from the body of the epistropheus And in this case I was led into error But looking back to the diagnosis of the patient as determined before the operation and examining now the symptoms, of the patient I find certain features that should have led to the conclusion that the dens had remained intact

FIG 3 B



After operation

the patient could turn his head and consequently execute movements involving the normal position of the dens Had the dentoid process been fractured the movements of the head could be effected but with very great difficulty. And then, the cases collected in 1913 by Prof Pokotilo and in 1918 by Prof Schenk testify to the fact that patients with anterior subluxation of the atlas are not infrequently so helpless in regard to their head that they are obliged to hold it in their hands Possibly this may be one of the symptoms of the fracture of the dens, inasmuch as the head is poised on that process as on a vertically set axis

However that may be in the case under discussion I assumed the occurrence of both fracture of the anterior arch accompanied by an anterior subluxation of the atlas and fracture of the dens As the condition of the patient failed to improve in spite of an application of a plaster bandage or treatment by extension, and he was suffering for a whole year, while his case latterly became worse, and as I knew no way of helping him by conservative methods, I thought I would endeavour to relieve him by means of an operation

Plan of the Operation

The atlas is displaced forwards, the ligamentum cruciatum being strained A further slight anterior slip of the atlas not only could but would lead to a rupture of the ligamentum cruciatum, compression of the medulla, and death of patient Hence the crux of the intended operation would consist in taking measures to avert the possibility of an ensuing compression of the medulla It thus becomes evident that to gain that purpose the anterior arch of the atlas should be removed This measure alone would permit the detached dens to move forward with the subsequent slipping forward of the atlas It seemed to me theoretically desirable to resect the dens simultaneously with the resection of the anterior arch of the atlas In such case the danger involved in the compression of the medulla would be averted The stability of the head after such an operation might be impaired, but if it was a new dens would be substituted by means of another operative intervention. This new process would have to be placed posteriorly and so devised that while losing its rotatory movements the head would obtain stability, for that purpose it would be necessary to imitate the operation of Albee and to set the superior extremity of the osseous graft against the occipital bone, under the spina occipitalis, and to join its lower end with a most convenient space provided by the bifurcation of the spinous processes of the cervical vertebræ, commencing with the second and concluding with, say, the fourth, fifth, or sixth Anyhow, the painfulness of the bony projection of the anterior arch of the atlas protruding into the pharynx clearly testified to the necessity of its removal

In order to accomplish the excision of the anterior arch of the atlas it is, of course, possible to manipulate through the oral cavity But no surgeon desirous of performing an aseptic operation would willingly choose such a method There is another way of reaching the seat of operation Whoever has "aseptically" opened chronic retropharyngeal abscesses in children knows that the easiest and safest way to reach the affected region is to make an incision between the sterno-cleido-mastoideus in front and the trapezius at the back Reflecting forward the sterno-cleido-mastoideus with the entire vasculo-nervous fasciculum, the retropharyngeal space is rapidly reached without encountering any large vessel or important nerve and the abscess evacuated This was the way I intended to follow in performing an anterior laminectomy of the first cervical vertebra

It must not be forgotten that behind the dens lies the cruciate ligament, overstrained in cases of subluxation If this ligament gets ruptured as a result of an awkward movement of the head, which may always occur in spite of the greatest care on the part of the patient, so much the easier can such a contingency arise under anæsthesia, when all the reflexes of the patient are depressed, and when in the process of vomiting, for instance, violent movements of the head may ensue Therefore I was obliged to warn the patient of the danger To avert it as far as possible a plaster bed was prepared embracing one side of the head of the patient, the shoulder girdle, and the shoulder itself with the body as far as the margin of the ribs, the head and neck of the patient throughout the operation would be completely immobilised by means of this bed in which the side of the patient opposite to that operated upon is fixed As I intended to make an incision behind the left sterno-cleido-mastoideus the plaster bed was to embrace the right half of the head, neck and body The bed was prepared by the surgeon of the ward, Dr Matusov

The Operation Performed.

On Oct 25th, 1926, I performed the operation under chloroform and ether

The patient in his plaster bed was laid on the right side The incision was made along the posterior margin of the left sterno-cleido-mastoideus As a long incision for the sake of facilitating manipulations in the depth of the wound had to be applied, I had to sacrifice the accessory nerve of Willis Having dilated the muscles by means of blunt hooks, I succeeded in penetrating easily between them into the retropharyngeal space A long spatular speculum, with which the anterior part of the wound was reflected, was then introduced Palpation of the arch of the atlas as it projected forward was easily obtained I then commenced to manipulate with the chisel in order to chip off the arch Here I met with a serious difficulty Every time I set the edge of the chisel with my left hand against the apex of the arch of the atlas, protected as it was by the anterior ligament (I had no suitable raspatory for a wound of such a depth) and with my right administered blows on the handle of the chisel with a hammer, the edge of the chisel would slant off the slippery surface of the ligament I could obtain no useful advantage from the chisel and even risked perforating the separated mucous membrane of the pharynx

It should be noted that the wound was relatively deep To see anything in the depths of the wound was impossible I had to work in the dark and to trust to the sense of touch To set the edge of the chisel perpendicularly to the surface which was to be chipped off, the handle of the chisel had to be inclined anteriorly and towards the middle line, the chiselling plane lying somewhat to the front of the line of incision of the integuments In turning the handle of the chisel towards the middle line and anteriorly I pressed the instrument against the posterior margin of the sterno-cleido-mastoideus, whose resistance caused the handle of the chisel to turn back again That was one of the reasons why the chisel slipped off the surface operated upon after every blow of the hammer

To recede from this position and succeed in the intended operation I followed the advice of the assisting surgeon, Dr Nazarov, and acted in the following manner —

The index-finger of my left hand was introduced into the retropharyngeal space The dorsal surface of the finger protected and reflected the mucous membrane of the pharynx while the palmar surface pressed the extremity of the edge of the chisel to the surface operated upon With the right hand I kept the handle of the chisel in the requisite direction, while my assistant, Dr Nazarov, administered blows to the top of the handle In this way we very slowly approached the realisation of our object, and at last the anterior arch of the atlas with its anterior ligament was chipped off This part of the operation took about one hour

I could now easily palpate the anterior surface of the dens which was enveloped in adhesions I refused to try to move it, and could not determine whether it was fractured at the base or not

The wound was sutured, a small tampon saturated with iodoform being introduced into the retropharyngeal space To reach the retropharyngeal space is not at all difficult. But to chip off the anterior arch of the atlas was an exceedingly laborious process, which was caused, in my opinion, by the lack of a suitable instrument The retropharyngeal space after the anterior separation of the mucous membrane is a few centimetres long, and if operated upon should really be illuminated It would seem necessary for that purpose to provide the extremity of a specially designed long and curved dilator with an electric lamp protected by thick glass to ensure it from being accidentally broken while the chisel is being used I had to act trusting exclusively to my sense of touch For separating the anterior ligament and periosteum from the arch it would further be desirable to possess a suitable raspatory with a certain definite curve and attached to a long handle These instruments might, of course, be unsuitable, in order to prevent subsequent growth of callus at the site of operation it would possibly be wiser to have recourse to a chisel. But the chisel should in any case be of suitable shape, long and with a sharp and narrow edge, set on a handle somewhat curved back In that case collision with the posterior margin of the sterno-cleido mastoideus would be averted, and the handle would not interfere with the examination of the wound and the visibility of the direction of the edge The entire operation would then proceed under the control of the eye, and from being cumbersome and difficult, would become elegant and easily and rapidly accomplished

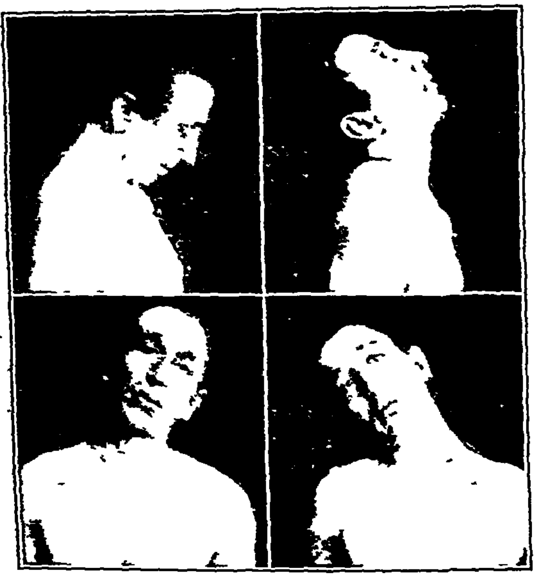
For many reasons over which I have no control I have no hope of being able to devise an armamentarium for the excision of the anterior arch of the atlas

Since, however the operation described will probably be found of use, I have no doubt that some surgeon will devise the requisite armamentarium, and by so doing will afford me great satisfaction.

Results of Operation.

The patient was removed to his ward in his plaster bed in which he remained for ten days However on the sixth day, while still in his plaster bed, he could already move his head slightly During the first three days he experienced pain deep to the pharynx, which interfered with deglutition On the third day after operation the tampon was removed The wound discharged a small quantity of bloody liquid The plaster bed was removed on the tenth day. On Nov 11th it was recorded that the patient moved his head from side to side freely without pain, but the power of inclining the head was limited.

FIG 4



Photographs showing range of movement after operation.

In Fig 2, an X ray taken after the operation, the fractured and projecting part of the anterior arch of the atlas is absent, having been removed by operation. The anterior longitudinal ligament of the vertebral column, interrupted at the seat of operation, can likewise be seen in the same radiogram Another detail, which could not be observed in the plate taken before the operation, can now be seen; a piece of bone has become detached from the lower part of the centrum of the second vertebra and has sunk down Thus besides the subluxation of the altas and the fracture of its anterior arch, a partial fracture of the centrum of the epistropheus had occurred In the plate taken before the operation this detached piece of bone could not be observed, as the whole picture was indistinct Fig 3 is a radiogram taken through the mouth after the operation It exhibits clearly: (1) lack of bone in the anterior arch of the atlas due to the portion resected at the operation; (2) a projection of the dens, much more sharply defined than the normal since the view of it is not obstructed by the anterior arch of the atlas No line of fracture at the base of the dens can be seen, the process being intact It was thus fortunate that during the operation I did not interfere with the process, though I believed then that it might be fractured and might have to be extracted later by means of a dentist's bayonet-curved forceps The integrity of the dens had evidently enabled the patient to execute lateral movements of the head before the operation

Photographs taken six weeks after operation show that all the movements of the head of the patient have been restored (Fig 4); he could move his head painlessly in all directions, whereas before the operation the head could be moved from side to side only with pain and in a jerky manner.

I think that the results of the operation are worthy of attention; and if the question is put, "Can anterior subluxation of the atlas be treated by operation?" I can give it but one answer. such an operation is not only achievable, but desirable and necessary, as it restores to the patient full control of his head, without producing any harmful result. In cases of fracture of the dens, it may or it may not be desirable to have it removed I am unable to come to a definite decision on that point But that subluxation of the atlas with fracture of the anterior arch and integrity of the dens should be submitted to operative treatment seems to be clearly demonstrated by the observations herein contained Thus it appears that in this category of injuries, rare certainly but serious, results can be obtained by operation which are not achievable by more conservative methods I must remind readers that the operation was performed one year after the injury, at the end of which a sharp aggravation in the state of the patient had occurred.

PHLEBITIS AND THROMBOPHLEBITIS

OF THE LOWER EXTREMITIES AND OF THE SUPERFICIAL VEINS OF THE LOWER ABDOMEN *

BY WILLIAM BAIN, M D. DURH., F.R C P. LOND , F.R C S EDIN.

IT is rather remarkable that in most of the text-books on medicine which I have seen phlebitis is either not mentioned or dismissed in a few sentences. Seeing that it is fairly common in gouty patients, and as a complication or sequela of infectious diseases, this is somewhat surprising.

It has been a subject of controversy whether phlebitis occurs with or without the formation of a thrombus, or whether thrombosis always precedes phlebitis. Hunter and his disciples stated that inflammation of the vein preceded the thrombosis, but Virchow in 1856 declared that thrombosis was the primary and essential condition, and that phlebitis was secondary There is probably a certain amount of truth in both these assertions. Phlebitis with thrombus formation is certainly the more common form

Varieties of Phlebitis

The varieties of phlebitis or phlebitis cum thrombus are · (1) Phlebitis migrans[1] Briggs[2] describes cases which he calls recurrent phlebitis of obscure origin His description of these cases bears a strong resemblance to the phlebitis observed in gout. (2) Syphilitic phlebitis which chiefly affects the adventitia of the vein (3) Phlebitis occurring in connexion with a septic wound Two and three will be excluded from further consideration. (4) Thrombophlebitis as a complication or sequela of infectious diseases, such as enteric fever or influenza (5) Intramuscular thrombophlebitis This variety is not mentioned in either Allbutt's or Osler's Systems of Medicine Certain specialists profess to believe that both phlebitis and thrombosis are due to micro-organisms or their toxins I will endeavour to answer these questions by the citation of appropriate cases

Ætiology.

Predisposing Causes—Thrombosis is supposed to be due to one or more causes, viz :—

(1) Damage to the lining cells of the vein

---

* Read before a meeting of the Harrogate Medical Society

[1] Schwarz, Gottfried · Phlebitis Migrans, Virch. Arch. f. Path. Anat 1905, clxxxii, 178

[2] Briggs, J B Bulletin Johns Hopkins Hospital, 1905, xvi, 228

(2) Retardation of the blood stream and changes in the blood increasing its coagulability When the endothelium is well nourished and there are no micro-organisms present thrombosis is unlikely to occur. Barcroft has shown the fundamental importance of oxygen for the life of the tissues.

(3) *Chlorosis*—Thrombi occurring in chlorotic subjects are probably due to changes in the blood The endothelium of the veins must be imperfectly nourished when there is a marked diminution of the hæmoglobin in the circulating blood

(4) *Gout*—Sir James Paget stated that in gout phlebitis "affects the superficial rather than the deep veins and often occurs in patches, affecting (for example) on one day a short piece of the saphenous vein, and on the next day another separate piece of the same, or a corresponding piece of the opposite vein It shows herein an evident disposition towards being metatastic and symmetrical; characters which, I may remark, are strongly in favour of the belief that the essential and primary disease is not a coagulation of the blood, but an inflammation of the venous walls" Sir William Roberts suggested that the presence of scattered crystals of sodium biurate in the blood may constitute foci around which thrombi may be formed a far-fetched theory Another writer suggests that gouty phlebitis is due to an intoxication arising from the alimentary canal Coates and Raiment estimated that the calcium in normal human blood was about 10 mg per cent In the blood of gouty subjects it varied from 16 mg per cent to 24 mg. per cent It must be obvious that this great increase in the blood calcium would render gouty subjects liable to attacks of thrombophlebitis

(5) Parturition, especially after severe hæmorrhage.

(6) Infectious diseases, such as enteric fever and pneumonia A peculiar feature is that in thrombosis complicating an infectious disease the specific micro-organism of that affection has never been discovered in the clot An American writer expressed the opinion that tobacco predisposes to phlebitis

Apart from toxins the most common exciting cause in my experience is a chill—more especially if this is immediately preceded by either mental or physical fatigue There are all grades of severity, from a simple phlebitis up to a complete blocking of the femoral vein The greater frequency of venous thrombosis in the left leg is attributable to the greater length and obliquity of the left common iliac vein and its passage beneath the right common iliac artery It has been suggested that the pressure of a distended sigmoid flexure or rectum may contribute to slowing of the blood stream on the left side

Symptoms

The initial signs of phlebitis and thrombophlebitis are as a rule identical when a superficial vein is affected A small patch of cellulitis over a vein can be seen, somewhat reddish, or purplish-red in tinge, and on gentle palpation a slight brawny thickening can be felt The history of the attacks is, however, different. In simple phlebitis the patient is generally unaware that there is anything the matter until he gets out of bed On walking he feels pain in the affected part In thrombophlebitis the patient awakes during the night with pain in some part of the leg, and if he has had a previous attack he can, with some assurance, suspect the probable diagnosis In simple phlebitis, when the cellulitis subsides, the vein will be found permeable, so that the patient may get up in five or six days It is a wise rule to keep him in bed for at least a week in case of a recurrence in the same or another vein With thrombophlebitis, after two or three days there will be felt one or more clots which will either become absorbed or organised so that the vein becomes permanently-occluded When a superficial vein is thrombosed the pulse and temperature are unaffected, unless the clot is extensive or septic The long saphenous vein has from 10 to 20 valves, more in the leg than the thigh A clot generally extends up to the next valve, but if the patient goes about it may extend further It has been stated that inflammation of the left saphenous is more painful than the right on account of the close proximity of the left saphenous nerve to the vein I have seen five cases of simple phlebitis occurring in gouty or rheumatic subjects where no septic focus could be detected My case-book shows a larger number of cases of thrombosis, in some of them without any detectable sign of infection. Instead of referring to the symptoms of the more severe forms of thrombophlebitis the better plan will be to describe cases illustrating special points in the different degrees of severity.

Clinical Records

CASE 1—A patient sat in a cold room until his feet were icy cold He awoke about 4 A.M. with *pain in the left leg* Ten grains of aspirin relieved the pain When I saw him there was a clot about the size of a small marble in the lower part of the left calf about 4½ inches above the ankle. On movement the pain was rather severe owing to the vein dipping beneath the fascia When the affected vein is on the inner side of the leg below the knee the pain, if any, is negligible unless the part is palpated rather too firmly Generally the patient is quite comfortable unless he exerts himself The clot completely disappeared in five weeks

CASE 2—Last March a patient had an attack of thrombophlebitis of the right circumflex iliac vein When I saw him some weeks afterwards there were four distinct clots to be felt On palpation they gave the impression of small indurated glands They have practically disappeared now—only a slight thickening remains About four months ago he had a patch of cellulitis over the right superficial epigastric vein It was about the size of a five-shilling piece On gentle palpation nothing could be detected except a slight thickening of the subcutaneous tissues Two days later there were three clots present in the vein They have not quite subsided yet Six weeks later he had a boil on his hand which was excised A culture showed the presence of the *Staphylococcus aureus* Examination of the blood was negative

CASE 3—A patient about 55 A gouty subject, had fibrositis of the lumbar and right gluteal regions and of the fascia lata for which he was having dry massage The masseur after a fortnight's treatment noticed one day that he had œdema of the right ankle, and asked him to see me at once He had no pain on exertion, and apart from the œdema there was no swelling of the cutaneous tissues I examined the calf of the leg carefully but failed to detect any tenderness On palpating the front of the leg he thought it was a trifle more sensitive over the anterior tibial artery compared with the other leg Three days before the appearance of the œdema he put on riding-breeches which were too tight and rode a bicycle for 40 miles The œdema disappeared in three weeks' time after complete rest His teeth had been extracted, and his nasopharynx appeared normal

Regarding œdema, the obvious explanation is that it is due to venous obstruction, to a filtration of the blood serum in consequence of the increase of intravenous and intracapillary pressure as a result of the blocking of a medium or large-sized vein This explanation is not quite so satisfactory as at first sight it appears The problem is a complex one, and there are certain undetermined factors at work which are interwoven with the processes of lymph formation and lymph absorption

CASE 4—A gouty patient caught a chill one evening While he was having a bath next morning he noticed the left calf was larger than the right This was confirmed by measurement On examining the leg he could not detect any tender spot There was no pain or discomfort in the leg He lay on a couch all day with the leg elevated, and at bedtime put his knee on a chair and slid it along to the bedside Next morning the left leg was nearly double the size of the other The doctor told him his femoral vein was blocked. During the four months he lay in bed he never had any pain in that limb, merely an intermittent sensation of tenseness over the shin

An interesting question in connexion with this case is, can there be phlebitis of a large vein without pain, or, *alternatively, can* thrombosis occur without the supervention of phlebitis? The vein remained blocked for 12 months when the œdema disappeared and the leg became perfectly normal in size It is one of the miracles of pathology how a vein obstructed for over a year can again become permeable

About six weeks after this attack, the patient was reading in bed one night and did not notice that the window was wide open until the right foot felt very cold; the affected leg was encased in cotton-wool from the foot upwards A hot water-bottle was applied immediately to the foot. He awoke about 3 A.M. with severe pain in the right calf Fifteen grains of aspirin taken two hours later gave complete relief, and the pain did not recur That day the doctor stated there was œdema of the ankle, and over the lower end of the tibia, but there was very little swelling of the leg—less than an inch. Previously the leg had been measured, to compare it with the left. If pressure was applied to any part of the leg there was marked tenderness, otherwise there was no discomfort except whem the leg was moved. The condition was diagnosed as intramuscular thrombophlebitis, this opinion being subsequently corroborated by a London specialist. The œdema did not disappear for eight months It should be mentioned that the patient's pulse and temperature remained normal throughout his illness, and that no septic focus was detected. This happened 10 years ago and both limbs have been normal in size ever since.

Years ago I saw a number of cases of phlegmasia alba dolens after parturition, influenza, and enteric fever Some of the patients had permanent enlargement of the leg, especially after exercise, due to œdema

Treatment

When the temperature is 102° F. or over it is advisable for a surgeon and physician to meet and discuss the treatment to be adopted If the temperature is over 101° and there are recurring rigors, the case should be seen by a surgeon also I shall only deal with those cases where the temperature is either normal or not over 101°

On examining a patch of cellulitis over a superficial vein, only the gentlest palpation is permissible on account of the danger, if a thrombus be present, that a portion of it may be detached; in fact, it is safer not to touch the affected part for the first three days The diagnosis cannot present any difficulty The chief essential is rest in the semi-recumbent posture when a superficial vein is affected, and in the recumbent position if a larger vein is involved I should like to stress the point that absolute rest is the important factor in treatment

The foot of the bed should be raised, and the so-called cradle used to protect the limb from the weight of the bedclothes A pad should be placed under the heel A hot fomentation of boric lint covered with yellow oil silk and lightly bandaged should be applied to the cellulitic patch If there is pain, lead and opium solution, or preferably glycerine of belladonna, may be used. If a deep vein be affected, other preparations have been recommended, such as, ouataplasme and antiphlogistine Shortly after the onset the whole limb should be wrapped in cotton-wool, or gamgee tissue, and kept in position by a many tailed flannel bandage This device can be changed every night or twice daily If pain still persists a cachet of magisal 7 gr, pyramidon, 6 gr, and caffeine citrate, 3 gr, may be given every four hours If four cachets do not give relief, a hypodermic injection of morphine should be used, but I have not seen a case requiring morphine The patient should be warned against sudden movements in bed It is the merest commonplace to say that particular attention should be paid to the alimentary tract both as regards a satisfactory evacuation of the bowels daily, and strict attention to dietetic restrictions the chief desideratum being a reduction in the intake

In thrombosis of a superficial vein the patient may get up to the commode placed alongside the bed, but if the femoral vein is affected, he must submit to the use of the bed pan I do not think there is any risk when a superficial vein is affected in using the commode, as the patient can slide on to the night-stool without jerking the affected leg, or putting his weight upon it The patient may be sponged daily with eau-de-Cologne, the back and gluteal regions should be thus treated four or five times each day to prevent bed-sores An intensely disagreeable symptom, becoming prominent after the sixth week, is an indescribable ache in the lumbar region It is more exasperating than a pain, because the latter one can relieve whereas the former resists more or less any remedial measures Air cushions are in most cases useless I have tried a large cotton-wool pad with the centre cut out, but it made the patient uncomfortably hot. In future I shall use a liniment consisting of menthol ʒ ii, lin belladonna ʒ iii, to lin chloroformi ℥ ii It is the most likely application to give temporary relief When the femoral vein is thrombosed gentle effleurage from below upwards may be prescribed two or three months after the onset, but it is quite unnecessary in thrombosis of a superficial vein

The question, "When may I get up?" is frequently asked It is wise to err on the safe side, and say from four to six weeks, if a superficial vein is thrombosed, but as regards a large vein the answer depends upon the severity of the attack, and the condition of the patient Even when the pulse and temperature are normal, and the patient feels quite well, it may be necessary to keep him in bed from three to four months if the femoral is completely thrombosed, as there is a considerable strain upon the superficial veins

Regarding drugs, Almroth Wright recommended citrate of sodium in milk; later on he substituted citric acid 20 gr. in water twice daily, which is quite a pleasant drink, and so far as I know cannot do any harm If a septic cause is suspected, collosal manganese orally has been recommended Apart from any therapeutic influence, the administration of a drug may have a psychological effect upon the patient, and in treating disease every little thing may be helpful; it is extremely difficult to assess the value of any subsidiary remedy.

If a patient has had more than one attack of phlebitis, he ought, if possible, to undergo the treatment at Bagnoles de L'Orne From the evidence the waters and baths of this place seem to possess peculiar properties in the prevention of phlebitis.

Clinical and Laboratory Notes.

A CASE OF RAT-BITE FEVER

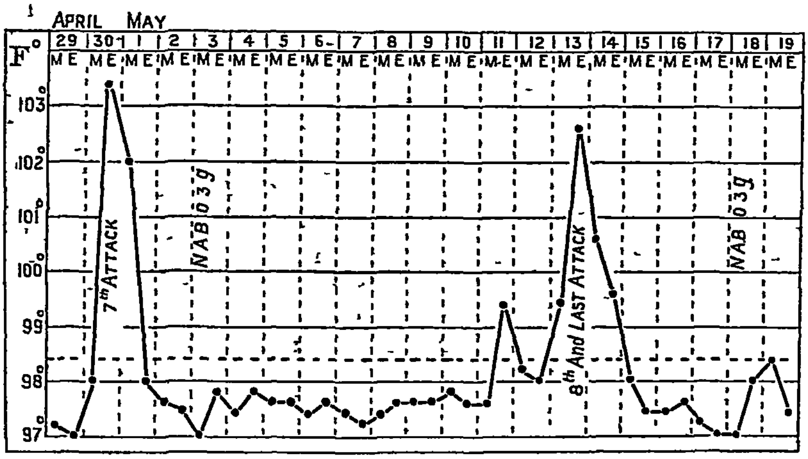
BY T. L HARDY, M D CAMB, M.R C P. LOND,
ASSISTANT PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM;
CONSULTING PHYSICIAN, EVESHAM HOSPITAL;
AND
H MEARNS SAVERY, M R C S ENG,
HONORARY SURGEON, EVESHAM HOSPITAL.

THE following notes of a case of rate-bite fever are thought worthy of record not only on account of the comparative rarity of the condition in this country, but also because certain signs usually regarded as typical were absent

J K, aged 25, a farmer, was first seen on March 14th, 1925, on account of headache, nausea, severe limb pains, and weakness of remarkably sudden onset His previous medical history was uneventful apart from a very mild attack of malaria during the war, from which he had completely recovered

On examination the temperature was 102° F. and the pulse-rate 120; the pulse was small and of poor volume The blood pressure was 100/80 He was sweating profusely, and a faint blotchy erythematous rash was noticed on the trunk and limbs The liver and spleen were not enlarged and the abdomen was soft and painless to pressure The lungs were normal and the urine was free from albumin and sugar A small bilious vomit contained no free hydrochloric acid The clinical picture was that of extreme prostration such as is seen in influenza, a diagnosis which was rendered more probable by the occurrence of several other cases in the locality After 24 hours the temperature and pulse were normal and the patient appeared himself again.

Eight days later these phenomena were exactly repeated, and on this occasion, in response to a leading question, he admitted having had a rather severe rat bite about two months previously. The bite had healed rapidly, and he had not connected the inciden with his subsequent illness A soundly healed painless scar was visible on the left hand, no enlargement of lymphatic glands was noted either on this or subsequent occasions A blood-count gave the following result red cells, 4,560,000 per c mm, hæmoglobin, 85 per cent.; leucocytes, 16,000 per c mm, of which 89 per cent. were neutrophil polymorphs In films stained by Leishman's and Giemsa's stains no parasites were seen, the only abnormality being the presence of many red cells showing punctate basophilia A broth culture was negative



Temperature chart in a case of rat-bite fever

Unfortunately, no other method for identifying the *Spirillum morsus muris* was carried out.

The patient continued to have febrile attacks every eighth day until on May 3rd, two days after his seventh, he was admitted to the Evesham Hospital and given novarsenobenzol 0 3 g intravenously. Following a slightly longer interval, nine days instead of seven, he had his eighth attack and a further injection of N A B, 0 3 g was given, since when he has been perfectly well

In view of the history, the long incubation period, the clinical phenomena, and the rapid response to treatment by N A B it can scarcely be doubted that this was a case of rat-bite fever, and we wish to draw special attention to the fact that at no time were there signs of recurrent inflammation in the wound, which remained healed and painless throughout, nor enlargement of the lymphatic glands Judging from the published accounts (1, 2, 3, 4, and 5) this is quite exceptional, if not unique, and adds to the difficulties of diagnosis where a prolonged incubation period and absence of all local symptoms combine to conceal the original infection

UNUSUAL MISDIAGNOSIS IN A CASE OF ACUTE INTESTINAL OBSTRUCTION

BY C E H ANSON, M R C S ENG,
HOUSE SURGEON, KING'S COLLEGE HOSPITAL.

THE following case is of interest as an example of an unusual error in diagnosis

A man, aged 65, was admitted to King's College Hospital on August 18th, 1926, with acute intestinal obstruction The acute symptoms were relieved on admission by an asafœtida enema. The patient gave a history of a dull pain in the hypogastrium for three weeks He had also been getting constipated, the motions becoming smaller in quantity and very hard, though of normal shape and colour There had been no diarrhœa, and no blood or mucus in the stools Defæcation had become increasingly difficult with much tenesmus Micturition was normal, except that the quantity of urine had diminished slightly three days after the onset of constipation.

Condition on Examination —Pulse-rate 84, temperature, 98 4° F. Abdomen distended and prominent, movements normal, no rigidity, no tenderness Hypogastrium dull to percussion, with shifting dullness in both flanks Liver, spleen, and kidneys not palpable On rectal examination a hard nodular mass about the size of a large egg was felt in the anterior wall of the rectum, 2 in, above the external sphincter It was not movable, and the surface felt as if it was ulcerated, but no bleeding occurred on examination. A diagnosis of carcinoma of the rectum was made and as obstructive symptoms increased, a colostomy was performed by Mr Cecil P. G Wakeley on August 20th

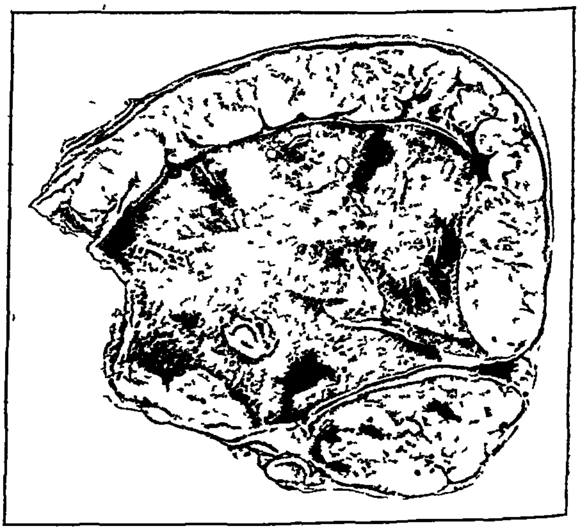
Operation —A paramedian incision 3 in. long was made through the left rectus muscle, and the peritoneum was opened A condition of diffuse carcinomatosis was found with small nodules over the small gut and colon, and also in the mesentery About three pints of dark-brown ascitic fluid was drawn off, and a colostomy performed. The gut was opened, a Paul's tube was tied in, and the wound was sutured and packed round with iodoform gauze and a powder of boric and salicylic acids to prevent ascitic oozing

Progress —On the day after operation the patient vomited 30 oz. of foul coffee-grounds vomit There was slight action of the colostomy, but although purgatives were given freely an action of the colostomy became increasingly difficult The liver and spleen became palpable on Oct. 4th, and the patient died on Oct. 23rd

Autopsy —Body was greatly emaciated; both lungs showed collapse and broncho-pneumonia at the bases Heart muscle showed brown atrophy

The peritoneal cavity was almost completely obliterated by adhesions and carcinomatous growth, and there were numerous small nodules on the abdominal wall and over the surface of the gut. A huge mass of carcinoma was found beneath the left lobe of the liver, slightly adherent to it and to the stomach, but not invading the stomach wall Beneath the right lobe there was a large abscess containing foul, greenish pus On examining the mass felt per rectum, it was found to be a secondary deposit situated between the rectum and bladder As it was obviously not the primary growth, the viscera were removed in toto with part of the posterior abdominal wall, they were hardened in 10 per cent formalin, and a detailed dissection was subsequently made

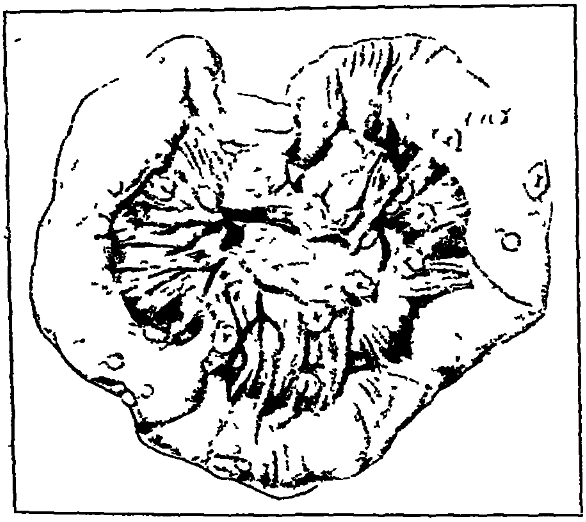
FIG 1.



Section through liver showing the growth surrounding the periphery of the organ in the form of a capsule, while leaving normal liver tissue, free from any secondary deposits, in the centre

The dissection showed a large, soft, fungating mass of carcinoma of the typical cauliflower variety filling the cæcum and occluding the ileocæcal valve. The large mass of growth, already referred to as lying below the left lobe of the liver, was found to be a huge secondary deposit in the preaortic glands Spreading out from it were numerous nodules in the mesentery which were almost confluent at its base, but became more sparsely scattered as the free margin was approached The splenic hilum was invaded by growth spreading from the region of the cœliac group of preaortic glands, and the periphery of the liver was invaded by a mass of growth which completely encapsuled the organ, the enclosed liver tissue being perfectly normal (Fig 1) The duodenum and stomach were normal, although part of the greater curvature was adherent to the spleen and to the mass of growth springing from the preaortic glands The pancreas, kidneys, and prostate were normal

FIG 2.



Coil of small intestine, showing secondary deposits in the mesentery which become more sparsely scattered as the border of the gut is approached also the superficial deposits in the peritoneum covering the surface of the gut

Microscopic examination of the primary growth in the cæcum showed a typical adenocarcinoma with very well-marked colloid degeneration The secondary deposits in the peritoneum over the small gut and colon, and invading the periphery of the liver, were of similar structure, as was also the mass lying between the rectum and bladder This deposit of growth had penetrated the muscular coats of the rectum and invaded the mucosa, being just about to ulcerate into the lumen of the rectum

Discussion.

This case offers an interesting example of misdiagnosis, the error being chiefly due to the unusual position of part of the secondary deposit—namely, between the rectum and bladder In the light of the above findings, it appears that doubts might have been raised as to the correctness of the diagnosis by the continuation of some degree of obstruction after colostomy and also by the evidence of extensive secondary deposits, although the primary seat of growth in the rectum had not yet ulcerated through into the lumen of the bowel. On the other hand in carcinoma of the cæcum, secondary deposits are usually late in appearance, and, moreover, relief of obstruction occurring at the ileocæcal valve would not be expected to follow the operation of colostomy

There seems little doubt that in this case the original attack of acute obstruction relieved by colostomy, was due to the combined action of the growth obstructing the ileocæcal valve and the secondary mass narrowing the lumen of the rectum below The failure of the colostomy to act freely and the subsequent increasing obstruction were due to the primary seat of growth obliterating the ileocæcal valve more and more completely until finally almost complete obstruction again resulted Another unusual feature is the fact that there was a comparatively early and typical primary growth in the cæcum, with very extensive secondary deposits all over the peritoneal cavity

The case presents rather a striking example of the spread of the carcinoma by at least two well-defined and separate paths—viz, peritoneal and lymphatic spread The peritoneal spread is shown by the presence of small nodules in the peritoneum of both the anterior and posterior abdominal walls, while the secondary nodules situated on the surface of the small gut were also seen in the peritoneum and even microscopic examination showed that only the outer portion of the muscular coats of the gut had been invaded, the mucosa being quite intact A peritoneal spread, moreover, offers the only satisfactory explanation of the rare phenomenon of a complete carcinomatous capsule surrounding the liver and infiltrating its periphery for about an inch, while the central portion was left completely normal with no trace of any secondary deposit in its substance The mass lying in the recto-vesical pouch which lead to the error in diagnosis was due either to direct peritoneal spread or to a small mass of carcinoma cells becoming detached into the peritoneal cavity and then falling into the rectovesical pouch, there undergoing development. The lymphatic spread is shown by enlargement of the ileocolic groups of glands, which could be traced upwards until the huge secondary mass lying in the superior mesenteric group of preaortic glands was reached Further lymphatic spread from this point along the superior mesenteric afferent lymphatics was shown by the nodules of growth becoming more sparsely scattered through the mesentery as its periphery was approached (Fig 2) while at its base they formed a large confluent mass of carcinoma as already described The deposit at the splenic hilum was due to the permeation of growth from the superior mesenteric group to the cœliac group of preaortic glands and thence along the afferent vessels to the splenic hilum

It must also be mentioned that two small secondary deposits of growth were found *in* the sternum, opposite the seventh left and third right ribs respectively. This would appear to indicate some dissemination of the growth by the blood stream, although no further evidence of such a path of spread could be found. It is moreover, rare to find secondary carcinomatous deposits in bone where the primary seat of growth is the cæcum

I wish to express my thanks to Mr. Cecil P. G. Wakeley for permission to examine and record this case.

A NOTE ON THE
RELIEF OF MIGRAINE
BY THE ADMINISTRATION OF CONCENTRATED SALTS

By H C ROOK, M.B, B S LOND,
PHYSICIAN TO WORCESTER GENERAL INFIRMARY

THE treatment of migraine has taken many forms, both before and since E Liveing published his celebrated monograph The old idea that it was hepatic in origin has gradually given way to the modern theory of fatigue, eye-strain, or some endocrine defect. It would appear that a combination of the old and modern theories is the correct view. and that migraine, at any rate in a percentage of cases, is caused by a hepatic toxin, which in predisposed subjects may be produced by nervous over-action or inhibition Explanation of the action of this toxin is undoubtedly difficult, but migraine occurs chiefly in people with a highly sensitive nervous system, and it should be remembered that toxins both organic and inorganic, often show a predisposition to pick out and attack certain portions of the nervous system

The cases observed belong to Liveing's second type. They are consecutive, and none of them below failed to respond immediately to the method described. So long as treatment was continued the attacks completely disappeared or only showed as transient headaches without prostration or vomiting, but it was noticed that the first three cases ceased treatment after a time, to resume of their own accord when the symptoms reappeared The shortest time which the condition had lasted in any of these cases was 15 years, and every kind of treatment had been previously tried without success, except that in two cases massive doses of sodium bicarbonate had given relief for periods up to three months Both had subsequently failed to respond to this, and for a time the attacks became more severe

Particular attention is called to Case 3, in which, owing to marked distaste, cholecystenterostomy was decided on, with a view to direct drainage of the gall-bladder At operation, however, this was found to be very small, tightly tucked up under the liver and surrounded by adhesions, there were no gall-stones This was most unfortunate, since had the operation been completed and resulted in improvement, it would have been additional evidence of hepatic origin

Clinical Records

Case 1—Female, aged 65, married, no children An old Army nursing sister Migraine attacks about every three weeks or a month for 40 years Was free from attacks for three months on one occasion when she took large doses of bicarbonate First came under treatment in 1924 No attacks as long as treatment is continued but relapses if discontinued, but the attacks are not so severe General condition much improved Complexion, which used to be sallow, now a much better colour

Case 2—Female, aged 40, married, two children, one a girl, healthy, and one a boy, aged 10, who suffers from severe acetonæmia with occasional outbreaks of bullous urticaria papulata She first came under treatment in 1924 and showed immediate improvement, but owing to hæmorrhoids stopped treatment, after which the attacks of vomiting and hemicranial headache returned but not so violently Under modified treatment she has now had no attacks for 12 months General condition and complexion much improved and is now putting on weight Her mother and sister are similarly affected

Case 3—Female, aged 45, married, two children, one (boy) suffers from acetonæmia and has had attacks of urticaria papulata Frequent attacks of migraine since a girl, with vomiting for four or five days at a time Highly neurotic No attacks as long as treatment is continued General condition improved but does not persist with treatment owing to distaste Operation (supra)

Case 4—Female, aged 32; single Frequent attacks for many years, latterly every two to three weeks She has not long been under treatment but has had only one slight attack in the last six months and this was due to domestic worries

Case 5—Female, aged 35, married, no children Attacks of migraine since a girl and when first seen occurred fortnightly Dr B St Clair Roberts examined her eyes and reported no want of muscle balance or astigmatism Her father has recently had a stroke and this caused some return of headaches, but they are not so prolonged nor are they now associated with vomiting She again has only lately come under treatment but has had no real migraine attack for five months

It is unfortunate that the effects of fatigue and worry are so easily demonstrable in migraine and this has diverted attention from the real source of trouble—the liver Every one of these cases suggests a temporary poisoning of the nervous system and in the course of time the affected nerve cells become sensitised so that a relatively slight stimulus will originate an attack

Bennett and Venables showed that anxiety and worry affected the secretion of gastric juices in hypnotised subjects and it is not difficult to imagine that in patients with a low liver efficiency and a sensitive nervous system, some comparable inhibition takes place, resulting probably in acetone or one of its immediate derivatives being absorbed by the blood stream This was first noticed in the breath and in the urine in 1923, and formed the starting-point of the present investigation About the same time Venables's modification of Lyon's concentrated salts method of emptying the gall-bladder was first published, and this forms the basis of treatment.

Treatment

1 ℥ ii.–℥ iv of a 50% solution of magnesium sulphate is given one hour before rising, and following this, the patient is instructed to lie semi-prone on the right side

2 At the end of the hour a large tumblerful of hot water or hot weak tea is taken This is most important, since if the salts are not evacuated within two or three hours, a feeling of intense depression is produced which may result in an attack

3 Each case must be treated with regard to individual peculiarities and it is usually sufficient to give the concentrated salts once a week or once a fortnight, but they may be necessary twice a week at the commencement of treatment

4 The day or half-day previous to the salts is a starvation day, but this should be done not more often than once a week

5 Certain articles of diet must be strictly limited These are fats of all sorts, and in certain cases eggs, also chocolates, cocoa, coffee, and alcohol, especially spirits

6 Regularity of habit should be urged, and as far as possible, freedom from worry and fatigue

So many remedies have been tried and found wanting, that there must exist a healthy disbelief in any new form of treatment for this condition. That now described has the merit of being inexpensive and easy to carry out, and having regard to the immediate improvement which resulted, it is not too much to hope that with more general use a good percentage of cases of this condition will obtain marked relief by this treatment from their very distressing symptoms

Medical Societies.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

At a meeting of this Society held on March 25th, Dr Wilfrid Fox (Past-President) in the chair, there was a discussion on the

Place of Venereal Disease in the Medical Curriculum

Dr J H Sequeira said that in the combat against venereal disease—especially syphilis—the best investment was a high standard of knowledge throughout the profession In his early days it had been everywhere the custom for the surgeon to deal with venereal diseases in their initial stages, it was in the surgical out-patient department that the student was taught the differential diagnosis of primary syphilitic lesions as they affected the genitalia, but not all surgeons paid attention to blenorrhagia and its complications The surgeon also dealt with the secondary manifestations of syphilis and gummata when they involved accessible regions On the whole the result was satisfactory, as most of the men who had spent six months in the out-patient surgical clinics went into practice possessing a fair knowledge of diagnosis and treatment of the early, and some of the late, manifestations of syphilis And a share in the instruction was taken by the ophthalmic and dermatological departments But there was no compulsion on students to attend the skin department, and most of them were insufficiently instructed in the diagnosis and treatment of venereal disease in its earlier stages In those days the physician stood sublimely aloof from the more sordid aspects of syphilis; he only took an interest in the results of spirochætal infection when life was gravely threatened Dr Sequeira then recounted the events which culminated in the Royal Commission on

Venereal Disease, and said that before the Report of the Commission was issued Mr Frank Kidd had developed the treatment of gonorrhœa on modern lines at the London Hospital Genito-urinary Clinic and he himself had done the same for syphilis in the skin department.

An Ideal Course on Syphilis.

An ideal course on syphilis, said Dr Sequeira, would include contributions from the bacteriologist, serologist and pathologist, with demonstrations by the dermatologist, general physician and surgeon, neurologist, ophthalmologist, and laryngologist. Such a course was given in the early part of 1914 at London Hospital to post-graduates and senior students. It was a great success, but the war prevented its repetition. Then came the inauguration of a special service to deal with venereal diseases, the prime objective of which was to cope with the greatly increased incidence which followed war.

It would be generally agreed that the newly qualified practitioner should be able to diagnose at sight a straightforward case of primary or secondary syphilis and to take blood for a Wassermann test, or a specimen of serum to send to a laboratory. He should have been shown diagnosis by dark-ground illumination, but Dr Sequeira did not think that many men should be expected to give a satisfactory diagnosis by this means if they had left hospital some considerable time before. Also the practitioner should have learnt the technique of intravenous injection and the dangers and complications attending it. Everyone would admire Colonel L. W. Harrison's efforts to make of every general practitioner a venereal expert, but even what he described and the expensive apparatus he recommended did not apply to many general practices.

In cases of suspected gonorrhœa the student must learn to take the laboratory specimen, and must have some acquaintance with the technique of treatment, though it seemed advisable that care should be taken to check the wholesale irrigation which swelled the number of attendances in the clinics and which, he was credibly informed, materially helped the birth control movement by its effects on the posterior urethra.

State-aided Clinics and the Instruction of Students

Dr Sequeira could see no reason why the clinics supported by the State and local authorities should not be used for the teaching of students, but admittedly difficulties were encountered in practice. The kind of difficulty he had in mind was illustrated by the following incident. The staff responsible for venereal treatment at a hospital met representatives of public bodies to discuss developments requiring money, and the medical representatives were warned, before the meeting, that the question of teaching facilities must not be introduced into the discussion, otherwise the funds would not be forthcoming. One of the gentlemen who answered Dr. Sequeira's questionnaire mentioned that, by agreement with the officials of the financing bodies the medical officers did not give long demonstrations which would suggest to the patients that they were teaching students, and that students who were clerking in the venereal disease departments were given the title of "clinical assistant." Why, he asked, should there be this atmosphere of dissimulation? To instruct students there must be adequate opportunity—i.e., sufficient cases. It was said that the number of patients attending a clinic depended on the way that clinic was advertised. But the great medical schools should have the preference, as only in them could the greatest number of medical practitioners be taught. All should be run on equal terms. He asked whether it was proposed to teach venereal diseases at certain centres, as fevers were taught at the Metropolitan Asylums Board Hospitals. He hoped not, as the student's curriculum was already over-full and it would be disastrous to extend it. The time usually allotted in the schools for attendance in the venereal disease clinics was three months; some schools required attendance at 12 demonstrations. Attendance was now usually compulsory before the student presented himself for his final examination, but at one school it was still optional. In most cases the student's fifth year was regarded as the most appropriate stage for this venereal disease instruction.

Conclusions

Dr. Sequeira wished there were no special place for venereal disease teaching in the student's curriculum; there should be adequate instruction in the diagnosis and treatment of syphilis in all its stages. He held that the student was best taught about the primary stage and the cutaneous manifestations of the disease in the skin department. Adequate instruction should also be given in the diagnosis and treatment of gonorrhœa. If for administrative purposes, nothing better could be proposed than the making of ad hoc clinics, he urged that the heads of these departments should be part-time officers having a wide outlook and he would prefer that they should be younger members of the staff of a teaching hospital. Nothing could be worse he thought than the production of a class of venereal disease specialists locked up in their own narrow sphere whose efficiency was gauged by the increasing number of attendances, absence of complaints and optimistic reports.

Discussion.

The **CHAIRMAN** said that he had always held that the success of a scheme depended largely on the man. In the early days venereal diseases were taught by the surgeons, who were very bad at it: it had been a revelation to him when he went to the St. Louis Hospital, Paris, for a course of instruction on the subject. Many of the devices at clinics were employed to induce patients to undergo treatment, and if it were thought there was anything like experimentation by students many would be shy of coming, and would go to quacks. One difficulty was that at the hour when clinics were usually held the student had finished his day's work. But when the student attended there must be plenty of cases.

Mr **WANSEY BAYLY** thought that students should be taught the importance of radiography, as sometimes syphilis left sequelæ which X rays revealed.

Sir **JAMES DUNDAS-GRANT** said that in a startling number of cases syphilis was found to be the causal disease; it might be overlooked for instance, owing to the respectability of the patient. A tendency to give a hopeful prognosis in syphilis often had untoward results.

Colonel **L. W. HARRISON** said that he gathered that Dr. Sequeira would have no special place in the curriculum for the teaching of venereal diseases but that the student should be taught about them in all departments of the teaching school. That had been the custom in the past, and the result had been that one great cause of the spread of these diseases was lack of knowledge by doctors passing out of the medical schools. This was bound to be the result of teaching the subject in fragments. It was now too large to be divided up; it should be grouped into one department. The knowledge of the average man to-day was greater than formerly, and this was because the subject was taught where cases of venereal disease mostly congregated. Nowadays it was particularly important that the teaching should be in these centres for arsenobenzol quickly changed the features of the disease in a patient. He would teach venereal diseases in a venereal disease department starting almost from the first with the laboratory. It was very important that the student should appreciate the pathological as well as the clinical side—that he should thoroughly understand what was taking place inside the patient. It was generally agreed that the standard of diagnosis and treatment of these diseases in the Army had been raised from the date of the establishment of the school in connexion with the hospital in Rochester Row And the experience was that the clinics were better managed by men who had been taught in special venereal disease clinics and hospitals than by those who had been taught in a number of different departments in a general hospital In his own department he found no difficulty in teaching, neither had he difficulties with patients He thought the fear of patients taking offence, or of a pledge of secrecy being broken, was nothing more than a bogy

Dr H M **HANSCHELL** thought that venereal disease should be taught in the department which was in the position to treat it best—namely, the venereal disease department The house physician in a hospital had many other things to attend to, and would find it a nuisance to administer the drug, a drug, moreover, which he did not yet know enough about. Even in dermatological departments of hospitals he did not think it was usually taught efficiently Hospital staffs seemed to welcome having a venereal disease department to which cases could be transferred for treatment, and where students could see cases from the beginning to the cure

Dr W J **O'DONOVAN** emphasised the importance of teaching principles, which was of more value than teaching syphilis as syphilis. Some of the manifestations of this disease came primarily into special departments Acute iridocyclitis, in which there was a red and painful eyeball was as dangerous to sight, if not speedily treated, as was glaucoma Its differential diagnosis must be taught with that of other ocular lesions, and this teaching, along with the appropriate treatment, could not be given efficiently in a venereal disease department It was impossible to escape the necessity of teaching syphilis in every department of a teaching hospital In the matter of treatment, however, a special claim could be made for beds The principle that venereal diseases must be kept separate implied that no one should take part in their treatment except the member of the staff in charge of the special department for them He must run the whole department with all the specialties involved

Dr A M H **GRAY** thought that a practical mean could be found between the views of Dr Sequeira and Colonel Harrison All agreed that it was essential to have a properly organised treatment department, and the only question was as to diagnosis He felt that it was a great advantage for the student to see cases of syphilis in conjunction with cases of other diseases It would be a tragic thing if syphilis were to be entirely removed from the various special departments It had been his experience that in some hospitals the genito-urinary surgeons did not take much interest in acute gonorrhœa, and many cases of it were sent straight away to the treatment department Hence it was important that the student should attend that department, not only to see early cases, but also to follow up the treatment He had found but little difficulty in getting students to attend evening clinics, but they did not come as regularly or as often as they should It would be different if questions on the subject were set in the examinations, which it was the students' immediate objective to pass Attendance at his own clinic was compulsory, but the compulsion was not drawn too tightly.

Dr. **DENNIS VINRACE** said that every practitioner should know something about every disease, and a specialist should know all about his own department Syphilis, he thought, had usually more importance attached to it than it deserved, and prevalence of these diseases had also been much exaggerated If a man wished to specialise in them he should obtain an appointment as house surgeon at a V D. hospital, or as assistant in a clinic

Dr **MORNA RAWLINS** said that she found the attendances of students at the clinics good, and there seemed little difficulty in getting patients to come But gonorrhœa in women was difficult to demonstrate to a number of students

Major E C **LAMBKIN** spoke of the disappointment in Army medical circles when the special hospital at Rochester Row had to be closed, as the subject had not been properly taught in the Army until the hospital was organised Syphilis had now practically disappeared from the Army and only half a dozen beds were needed for it. Each special venereal hospital should have a special venereal laboratory For teaching purposes, he thought that V D cases should be concentrated in one special department

Colonel E G. **FFRENCH** said that he was a great believer in having special departments for these subjects in the hospitals, and favoured attendance at them being made compulsory. The general practitioner nowadays treated venereal disease himself instead of sending cases to the specialist

Dr. F. J. H. **COUTTS** said it was highly important that the general practitioners of the future should have a real knowledge of venereal diseases If a student was not taught differential diagnosis when he was passing through special departments there was something wrong with the teaching

Dr **DOROTHY LOGAN** said that at one time syphilis was met with in the surgical out-patients, in the medical wards, in the eye department and elsewhere, but there was no means of getting a continuous idea of the disease, such as the special department could now put before the student She agreed that all departments should combine in giving this knowledge.

The **CHAIRMAN** reminded the meeting that the prime object of the Bill which was brought before Parliament had not been to secure tuition of the medical student Training centres had been instituted by far-sighted people who knew of the ravages wrought by these diseases after all great wars, in order to cut down the incidence rate to the lowest possible figure And the clinics had certainly justified themselves In the campaign very great help was given by the lay press The coöperation of various specialists was required in order to demonstrate differential diagnosis The policy of the Society had been to secure the help of those not specially interested in venereal diseases as a safeguard against an exclusive specialisation

Dr **SEQUEIRA** briefly replied, reminding his hearers that his theme had not been the training of venereal disease experts, but the tuition of the medical student in those subjects

Dr **HANSCHELL** showed a case of

Climatic Bubo

The patient was a seaman (white), aged 43, who said that 20 years ago he had a wart on the glans penis It had been cauterised, and left a scar He had never had any other lesion about the genitalia. Nine weeks ago he was in Mauritius, and seven days after coitus the glands in the groin began to enlarge and become painful He was ill, and had to cease work At present there was nothing to be seen about the scrotum or penis His temperature varied between 99° and 100° F, the Wassermann was negative, and the blood did not contain filaria Climatic bubo, said the speaker, was fairly common in the tropics, and it seemed to be a venereal disease, because nearly always there was the history that it occurred a short time after connexion It had not yet been reported in a woman In men it was commonest in the uncircumcised A specific organism had often been searched for, but so far had not been discovered The usual treatment was to excise the infected glands, but it was found that they were all involved, and deep down After such large removal he had seen elephantiasis of the penis supervene The best treatment he had found was the intravenous injection of typhoid bacilli, this caused subsidence in a few days, and the illness was limited to a week or two He used in this case a stock vaccine, and began with 100 million, intravenously with the man fasting The dose was repeated in four days

ROYAL SOCIETY OF MEDICINE.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE

At a meeting of this Section held on March 25th, Dr S Monckton Copeman, the President, who took the chair, opened the proceedings with a reference to the recent death of Dr John Brownlee

Dr. W S McClure (Manchester) read a paper on the

Incidence of Pneumonia

During the last ten years, he said, 398,523 deaths from pneumonia had occurred in England and Wales The mortality was greater in the North than in the South, and greater in urban than in rural districts. Any rise or fall in the rate in England and Wales was shared alike by the North, the Midlands, and the South, there was, therefore, some factor, common to the country as a whole which influenced the prevalence of this disease Mean air temperature was closely correlated with mortality from pneumonia, but climatic conditions were not responsible for the heavier incidence in the North. Fog was a minor and unimportant factor, but contributed to the occlusion of light from towns, absence of sunlight lowered the human vitality, though there was no evidence that it was a determining cause of pneumonia. Relative excess of the disease in the North was equalled by the excess of other infectious diseases and was due to greater aggregation of the populace The greater the density of population in any area the greater the mortality from pneumonia Overcrowding in areas and in individual houses was the essential factor responsible for excessive incidence of the disease The remedy, therefore, was in the progress of housing and town-planning schemes In the meantime every additional open space provided in a town and every overcrowded area dealt with would, of a certainty, tend to reduce mortality from pneumonia.

Dr G Clark Trotter considered that the care taken of children had more to do in protecting them from pneumonia than the weather had to do with causing it

Dr Major Greenwood said that there was forthcoming a paper on pneumonia in London which seemed to show that overcrowding was more likely to be the cause of pneumonia in children, and weather the cause of pneumonia in the aged.

Sir William Hamer pointed out that such a disease was not likely to be due to a single cause, adding he had been impressed by the suggestion that pneumonia was often preceded by a cold.

Further discussion followed.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

A meeting of this Section was held on March 18th, Dr R J Rowlette (in the absence of the President) in the chair

Dr A R J Dungan read a paper on the rôle of the

Acetone Bodies in Diabetic Coma.

After a brief review of the literature, showing that the actual part played by the acetone bodies in producing the symptoms of diabetic coma was unsettled, Dr Dungan described experiments demonstrating that dogs and cats could be free from symptoms while having in their blood concentrations of acetoacetic and β-hydroxybutyric acids greater than those commonly found in human diabetic coma From this it was concluded that neither of these acids was likely to exercise a direct toxic effect on this condition The experiments, however, also showed that with the former acid, and probably also with the latter, when sufficient had been administered to a dog the result was a curious delayed intoxication leading to prostration and death. The animals commonly died at a time when acetone bodies had almost disappeared from the blood, and one of the features of the intoxication was a resistance to the action of insulin, such as occurred in human diabetic coma Dr Dungan suggested that this latter condition might possibly represent a similar indirect intoxication with one or both of these acids He described further experiments with acetone, showing that its effects were totally different from those of acetoacetic acid

Dr H. F Moore referred to the detailed and prolonged observations of which Dr Dungan's paper was the fruit

Dr A R Parsons asked if there was any danger of producing hypoglycæmia in a case of diabetes by pressing insulin when the urine was full of acetone and diacetic acid but there was only a very slight amount of sugar present

Dr H R Micks referred to the resistance to insulin which was sometimes met with, apart from ketosis, and asked what caused this resistance He mentioned a case recently reported, in which insulin had done very little towards lowering the blood-sugar, and said that it looked as if there was something else in the body, not a ketone, in diabetic cases which interfered with the action of insulin

Dr. E T Freeman asked if the effect of the ketone bodies in dogs in the advanced stage of diabetes was at all comparable with what it was in human beings, and if ketone bodies formed as rapidly in dogs as they did in human beings

Dr Dungan, in reply, said that cases of diabetic coma had been rather rare in the hospital in which he had worked in America. When they did occur the patients were given massive doses of insulin, and ketosis disappeared almost immediately Large doses of insulin should not, in his opinion, be given to a patient who had acetonuria, but was not in definite coma He did not know what caused the resistance to insulin in some patients, unless it was gross pancreatitis or carcinoma

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH

At a meeting on March 15th Dr L H Bryson described a series of cases of herpes zoster which had come under his observation during the past seven years In contrast to Head's record of age incidence he had found the disease more frequent in patients over 25 He had discovered no epidemicity nor any relation to chicken-pox Pain was usually a marked symptom, and increased in severity with the age of the patient The pain might be referred to a position apart from the rash In one of his cases there was at first severe pain on the radial side of the left forearm, accompanied with hyperæsthesia, whilst the rash appeared on the chest over the distribution of second and third dorsal nerves The definite cutaneous and nervous lesions of herpes zoster, with their associated sensation, provided peculiar opportunities for the study of symptomatology If the symptoms of herpes zoster could be accounted for, they would throw light on all symptoms Dr Bryson pointed out that all afferent pathways were the afferent tracts of reflexes having some other end-result than sensation, that sensation was the concomitant of a reflex, and that the reflex involved in the nerve lesion was probably a cutaneous capillary reflex The skin lesion occurred over papillæ where the capillaries were most numerous Considering the nature of the lesion, it was curious that tactile sensation was not interrupted. Anæsthesia was not a symptom, whilst hyperæsthesia was usual He suggested that pain arose on the same reflex to which the thermal sensations were concomitant, in all likelihood a vascular one. Hyperalgesia was due to an interaction occurring in the neopallium between the impulses of normal tactile sensation and those arriving from the site of a lesion, not, as had hitherto been represented, occurring in the cord.

Reviews and Notices of Books.

EXOPHTHALMIC GOITRE

By John Eason, M.D., F.R.C.P. Edin., Physician to the Edinburgh Royal Infirmary. Edinburgh: Oliver and Boyd. 1927. Pp. 215. 12s. 6d.

This is a notable addition to the literature of thyroid disease, being a broad survey in which recent additions to our knowledge have received critical attention. It will be welcomed by all who are interested in clinical medicine.

The volume is divided into two parts, of which the first deals with anatomical and physiological considerations and with the clinical examination of the thyroid gland. Part 2 is devoted to the clinical features of the diseases which are now classified under the title of exophthalmic goitre, and to their pathology, pathogenesis, diagnosis, and treatment. As the author points out, ætiological and pathological considerations now show that the Graves's disease syndrome is a unity only in the same sense as is Addison's syndrome. In each case various causes and *various pathological processes are associated with a* well-defined clinical picture, the essential pathological change affecting the thyroid in one and the adrenals in the other. Just as syphilis, tubercle, atrophy, or malignant disease may each give rise to Addison's syndrome by restricting adrenal function, so also Graves's disease is the result of the action of a variety of causes which stimulate thyroid function. These factors all receive full consideration, and since the modern views are mostly set out in addition to those formerly held, the reader is able to consolidate his knowledge.

Sections of the book which require special mention include the chapter on pathology, in which the changes in the thyroid are fully discussed, both in terms of the terminology now in general use, and also from the point of view held by Scott Williamson and I. H. Pearce. Again, the clinical features are probably described more fully and completely here than in any other book dealing with the thyroid gland. Especially valuable are the sections devoted to the alterations in the heart and circulatory systems and particularly the blood pressure. The value of a knowledge of the pulse pressure in estimating the severity of the disease is emphasised. Other modern methods useful in the diagnosis of this condition are discussed, notably the estimation of the basal metabolic rate; this test is of considerable value in following the effects of various methods of treatment, but the author points out that when it is not available, observations of the pulse pressure are equally useful, and a number of cases are quoted to illustrate this point. In the chapter on treatment the reintroduction of iodine therapy is fully considered and the indications for its use and methods of administration are described in detail. The administration of insulin and glucose is also recommended in certain cases, and it is interesting to learn that the author considers this method of treatment to have a definite if restricted value in the treatment of Graves's disease.

PHYSIOLOGY

Principles of Human Physiology. Fourth edition. By Ernest H. Starling, C.M.G., F.R.S., M.D., Sc.D., F.R.C.P., Foulerton Professor of the Royal Society. London: J. and A. Churchill. 1926. Pp. 1074. 25s.

Starling's Principles of Human Physiology needs no introduction to our readers. The fourth edition embodies the result of all those researches which have appeared during the past five years which are of fundamental importance. We note an account of E. C. C. Baly's work on the photosynthesis of hexoses, a new section on Neutrality and Reaction with descriptions of the methods of measurement of hydrogen-ion concentration. The work of A. V. Hill and his pupils on the relation between work done during muscular contraction and the speed of muscle shortening, is summarised, also that of A. V. Hill and Meyerhof on the time relations, quantitative analysis, and interpretation of the heat production during and immediately following muscular contraction. Several pages are devoted to the highly important and interesting researches of Pavlov and his school on the formation, types, and properties of conditioned reflexes. The section on the vitamins has been enlarged, and that on carbohydrate metabolism extensively altered to include a description of the isolation and preparation of insulin, and the mechanism of its action in both the normal and diabetic animal. Further additions include an account of the work of Bolton on duodenal regurgitation during gastric digestion, of C. Mann on hæmolytic jaundice, of J. Barcroft on the function of the spleen as a reservoir for red blood corpuscles, and of J. B. Collip on the parathyroid hormone. The changes in the sections on the coronary circulation, cardiovascular reflexes, and on the mechanism of urinary secretion have been occasioned almost entirely as the result of researches in the laboratories of the author. In spite of these many additions and alterations the bulk of the book has been reduced. This has been made possible by the omission of much that belonged strictly to the sciences of chemistry and anatomy, and is extensively covered in the text-books dealing with these subjects.

The vast field of knowledge which modern physiology requires is admirably covered with a lucidity of expression which commands interest throughout the pages of this volume.

Neuere Ergebnisse der Physiologie. Von Dr. Phil. et Med. Ernst Gellhorn. Leipzig: F. C. W. Vogel. 1926. Pp. 447. M.30.

This volume has been compiled by the author on a background of 22 lectures on various physiological subjects, the choice of subject being determined by the degree to which recent investigation has advanced knowledge therein. Especial attention is paid to those branches of research which have yielded results immediately applicable to the interpretation of pathological states in man.

The book is thus suitable for the advanced student of physiology, and for those medical practitioners who desire to become acquainted with the results of recent researches. The first four chapters are devoted to the more modern conceptions of such physico-chemical phenomena as osmosis, adsorption, membrane permeability, and electrical changes in living tissue in so far as they are of present significance in the interpretation of biological phenomena. These chapters also form a valuable introduction to the work, described in the later sections of the book, in which an attempt is made to interpret the more complicated reactions of individual organs in terms of the more simple dogmas of physics and chemistry. The work of J. Barcroft on the spleen, of O. Loewi on the liberation of substances having an inhibiting or accelerating action on the heart, and of A. Krogh, U. Ebbecke, and H. H. Dale and Richards on the capillaries, is clearly outlined. In connexion with this last subject, the author appears to have overlooked the fundamentally important work of Lewis and his collaborators on the reactions of the capillaries of the human skin. Further chapters deal with the results of recent work on the vitamins, the glands of internal secretion, and on the kidney. The work of A. V. Hill, O. Meyerhof, and G. Embden on the physical and chemical processes underlying muscular contraction is set out in considerable detail in two valuable chapters. There follows an account of recent advances in our knowledge of the physiology of the central nervous system, including a valuable account of R. Magnus's work, and the volume is brought to an end by three chapters dealing with the physiology of the sense organs.

The volume forms a useful survey of the recent work done in the particular branches of physiology with which it deals. Its bulk could have been considerably reduced had some of the papers referred to been examined more critically, and had the interpretations placed by authors upon the results of their experiments been less readily accepted. However, to winnow the chaff from the wheat of scientific literature is a time-consuming and wearisome task, and the fact that references to current literature are, if anything, too extensive, will not be resented by readers who wish to keep up to date without having to study original articles. The printing, paper, and illustrations are excellent.

EARLY DIAGNOSIS OF THE ACUTE ABDOMEN.

Fourth edition. By ZACHARY COPE, F.R.C.S. Eng., M.S. Lond., M.D., B.A., Senior Surgeon to Out-Patients, St. Mary's Hospital, Paddington. London: Oxford University Press. 1927. Pp. 237. 10s. 6d.

THE fact that this little volume has reached its fourth edition is evidence that it must have filled a want. The author has succeeded in reducing the problems of the acute abdomen to their simplest forms, and in explaining with remarkable lucidity the means at our disposal for their diagnosis. The volume is illustrated throughout with diagrammatic drawings which enable the eye to grasp their meaning at a glance. Any surgeon may peruse the volume with pleasure and will be sure to get fresh light on many points.

To the general practitioner who is called upon to deal with the acute abdomen this account should prove of the utmost value.

PROCTOLOGY.

Traité d'Endoscopie, Rectoscopie, Sigmoidoscopie. Second edition. By R. BENSAUDE, Medecin de l'Hôpital Saint-Antoine, Paris. Paris: Masson et Cie. 1926. Pp. 180. Fr.100.

THIS edition is in every way a great advance on the former one published in 1919. Interest will centre chiefly round the coloured illustrations, by Mr. Frantz, of proctoscopy and sigmoidoscopy. These illustrations, numbering 84, show both the normal and pathological conditions, and for clearness of detail and accuracy of colouring they are unsurpassed; the average level of excellence is high, but the illustrations of hypertrophied anal papillæ and tumours are exceptionally fine. The coloured plates are now interspersed with the text instead of being collected at the end of the book and are described in six languages.

The text has been largely rewritten and several new chapters have been added. The large number of black-and-white illustrations include a series of drawings of microscopical preparations. In the section on cancer the author describes the invasion of the rectum by cancers arising in the ovaries and uterus, but there is no mention, either in this chapter or in that on benign tumours, of adenomyoma of the uterus involving the rectum. Perhaps in the next edition the author will have something to say regarding this interesting and difficult condition. In the chapter on strictures of the rectum and colon there is no mention of diverticulitis. One would have liked to learn what the author considers characteristic of the view per sigmoidoscope of the lower end of a stenosing diverticulitis, and whether endoscopy affords any means of distinguishing this from a constricting carcinoma. Is œdema of the mucous membrane below the stricture more marked with diverticulitis than with carcinoma?

The final chapter on treatment describes zinc ionisation, the injection treatment for piles, and the application of radium in inoperable cancer of the rectum. The author advocates the use of diathermy for the removal of benign tumours, and illustrates an ingenious modification of the usual crocodile forceps and snare for use through the sigmoidoscope; the shafts of the instruments are insulated and allow diathermy to be applied through the jaws of the forceps or the wire snare. This would appear to permit of a very radical and efficient method of removing simple tumours, and is one which should be generally adopted in this country. A bibliography is appended at the end of the work.

THE CHARAKA CLUB.

Proceedings of The Charaka Club. Vol. VI. New York: Paul B. Hoeber. 1925. Pp. 145. $4.

THE Charaka Club, named after a Hindoo physician, called the Hippocrates of India, was organised in 1898 by a group of New York physicians who sought recreation and stimulation through excursions into literary, historical, and artistic fields. The sixth volume of the proceedings of this club opens with a delightful paper by Dr. G. H. Walton, who discusses the ever-present question of "Why other people and things annoy me so much," though it is not everyone who will have the courage to say in print as does Dr. Walton, "I wonder what it is I do that annoys everybody else?" Dr. Charles L. Dana contributes a little paper upon Dr. John Ursinus, a French medical man, who in 1541 published a work dealing with the medicinal properties of certain animals, and Dr. Dana credits him with being the originator of opotherapy. But remedies taken from animals were dealt with long before Ursinus's time by Pliny the Elder, in whose natural history will be found a number of astonishing prescriptions. An interesting paper is that by the late Dr. A. G. Gerster (the subject of an appreciation on p. 37 by Dr. Sachs) entitled, "A Letter on the Theory of Music." The paper does not say much about the theory, but it gives excellent advice as to how to appreciate music properly; Dr. Gerster evidently had a whole-hearted admiration for Bach, though curiously enough he makes no mention of his organ music. Dr. F. S. Meara supplies an admirable article upon that artistic printer, John Baskerville, whose editions of the Prayer Book and many of the Latin classics are well known. The first book to issue from the Baskerville Press was the Royal Quarto Virgil, published in 1757. There is a trap connected with this work which Dr. Meara does not mention, but all book lovers should know. An edition was reprinted in 1771 with the original date (1757) on the title page. The real 1757 edition may be known by the heading to the tenth book which reads Liber decimus Aeneidos, while the 1771 reprint has Aeneidos Liber decimus. Among the subscribers to the 1757 edition were John Fothergill, — Heberden, M.D.—i.e., William Heberden the elder, John Ash, M.D., Birmingham, who took two copies and was the first physician to the General Hospital at Birmingham, and sundry other medical men not so famous, such as — Akinside, M.D., who may, however, be Mark Akenside the poet physician. Among non-medical names those of Sam Johnson, A.M., Benjamin Franklin, Esq., F.R.S., of Philadelphia, and Thomas Gray, A.M., of Pembroke Hall, Cambridge, are notable.

MICROSCOPICAL ANATOMY OF THE IRIS.

By M. WOLFRUM, Professor at Leipzig. Berlin: Julius Springer. 1926. Pp. 218. M.16.50.

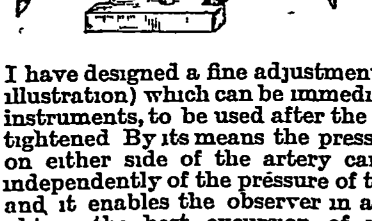
THIS is a section of the third chapter of the second edition of the Graefe-Saemisch Handbuch der Gesamten Augenheilkunde, a colossal work only to be compared in size and scope to the American Encyclopædia of Ophthalmology. As in that work, the sections are divided between a large number of collaborators. This volume is a considerable treatise dealing with the anatomy of the human iris, with several references to the anatomy of the iris in animals, especially apes.

There are still points concerning the *minute* anatomical structure of the iris that cannot be considered as settled. Fuchs describes the anterior surface of the iris as bounded by an endothelium, and Koeppe, from observations with the slit lamp, supports this. Wolfrum throws doubt on it, preferring to regard the so-called endothelial cells as merely flattened cells of the iris stroma Koeppe describes a lymphatic system under the so-called endothelium, which Wolfrum prefers to regard as merely the anastomosis of processes from the stroma cells With regard to the vascular system, Wolfrum finds that there is no true circulus arteriosus minor, the vessels usually described by this name being, in fact, mostly obliterated and derived from the fœtal pupillary membrane, microscopical remains of which, he tells us, are present in 45 per cent of normal cases as seen under high magnification. We do not gather his views on the circulus arteriosus major, which Thomson Henderson believes to be not actually arterial at all, but venous, looking upon all the vessels that perforate the sclera in the ciliary region as veins, contrary to the generally accepted teaching (Trans- Oph Soc, 1908, p 167) This is surely a point that ought to be cleared up in an authoritative work. With regard to the disputed existence of a dilator muscle of the iris, the modern view that the fibres adjacent to the posterior layers of the iris are really a dilator muscle is supported and may be considered proved. Some authorities have maintained that the cells of the stroma take part in the active dilatation of the pupil, but the conclusion of Wolfrum is that they do not, at any rate, in man With regard to pigmentation the physiologically important pigment cells exist almost exclusively in the posterior epithelial layer of the iris The pigment cells of the iris stroma, to which the colour of the eye is mainly due, are not normally present at birth in the white races, and when once laid down do not alter through life except as the result of degenerative or senile changes. The histological structure of the iris is of considerable interest in connexion with its relatively enormous capacity of contraction and dilatation, and with the alleged absorption through the crypts of its anterior surface and the circulation of the ocular fluid; but the physiological problems arising from this latter function, if it exists, are not discussed by Prof Wolfrum His contribution is valuable chiefly as a work of reference to the microscopical structure of the iris; the figures, especially some of cells under high magnification, are extraordinarily clear

New Inventions.

A FINE ADJUSTMENT SCREW FOR SPHYGMOGRAPHS AND POLYGRAPHS.

Sphygmographs and polygraphs, as ordinarily supplied, have a fixation screw for the tape and an adjustment screw for pressure of the pad on the artery, but there is no provision made for fine adjustment of the pressure of the apparatus itself on the wrist and thereby on either side of the radial artery In order to remedy this defect, I have designed a fine adjustment screw (shown in the illustration) which can be immediately fixed to existing instruments, to be used after the fixing screw has been tightened By its means the pressure of the apparatus on either side of the artery can be finely adjusted independently of the pressure of the pad on the artery, and it enables the observer in a very few seconds to obtain the best excursion of movement from the recording needle

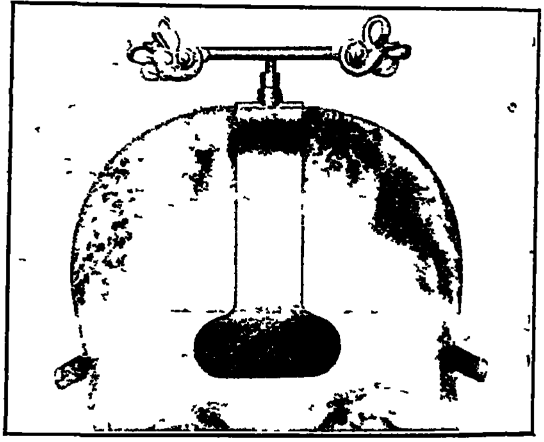


The special screw may be obtained from Messrs Arnold and Sons (John Bell and Croyden, Ltd), 50–52, Wigmore-street, W.1.

EDGAR F. CYRIAX, M D Edin.

MODELS OF THE LABYRINTH

MODELS of the labyrinth (King's College Hospital pattern), a specimen of which is shown in the illustration, have been made for purposes of investigating labyrinthine diseases and for teaching students. They are double natural size, and are made of Wood's fusible metal, which is sufficiently strong for ordinary purposes, the ampullary ends are painted in different colours in order to show them up It is not difficult to make reproductions of the semicircular canals and cochlea from one petrous bone, and it is also easy to make models of the labyrinth if accuracy is not desired But the intention of the present writers has been to produce a model which would be properly orientated As previously described in the Proceedings of the Royal Society of Medicine, the method used was to fix a hollow tube between the internal auditory meatus of a dry skull, and to hold this hollow tube in place by means of a rigid frame, which had bars clamped on to the side of the skull in such a way that the lower edge of each bar coincided with the Frankfort plane—that is to say, the upper margin of the bony external auditory meatus and the lowest point of the orbit. Metal was run through the foramen ovale of one side to fill the cochlea and semicircular canals of that side, and to pass across the hollow tube to the opposite labyrinth which was also filled, the hollow tube being rigidly held in place by cement The next step was to remove the bone and to extract the complete model in one piece The casting presented considerable technical difficulties, which were overcome by Mr. Shaw, who produced an intact model at the Royal Dental Hospital Enlargements were then made to double size, not by a modelling machine as had been hoped, but by free-hand work The models were made in silver by Mr Thomas, seal engraver and medallist, who exercised extreme care in getting details accurate Having secured the enlarged model, it was then necessary to arrange for reproduction in mass. This work was done successfully by Messrs Gerrard, furriers and naturalists, who made piece moulds and cast the two labyrinths together in Wood's metal The original frame was made by Messrs Mayer and Phelps, and they have made head frames with a pointer to lie parallel with the Frankfort plane in such a way that when the frame is on the head the labyrinth lies in correct orientation in all respects The patient's head can then be put into any position and the exact relations of each of the canals are seen, rotation and caloric tests can be carried out with the frame in position It must be remembered that there may be slight variations in the inclination of the canals in individual skulls



The whole apparatus of enlarged models and head frame can be obtained from Messrs Mayer and Phelps, 59, New Cavendish-street, London, W. 1

Products of Note

'Alkagen'

TRADE MARK

Tablets and Lozenges

An effective Antacid and Carminative for Hyperacidity and Flatulence 'Alkagen' is an efficient and pleasant preparation possessing the antacid properties of magnesium hydrate with the carminative action of oil of peppermint It provides a neutralising agent which is easily disintegrated, sufficiently soluble and prompt in effect, whilst unlike preparations of the alkaline carbonates or bicarbonates, *it does not cause* the evolution of carbon dioxide in the stomach

'Alkagen' Tablets In bottles of 60 120, 250 and 500

'Alkagen' Lozenges possess an agreeable, *mild* peppermint flavour they are particularly suitable for the relief of flatulence or the biliousness of children.

Issued in boxes containing 36 and 108 lozenges.

'Cystazol'

TRADE MARK

Tablets

A powerful Urinary Antiseptic. 'Cystazol' is a combination of Hexamine with Sodium Benzoate its action depends on the liberation of formaldehyde from the decomposition of the hexamine that takes place in the urine which has been rendered acid by the sodium benzoate moiety 'Cystazol' is employed with advantage *in cystitis, bacilluria* of all types, pellagra, gonorrhœa and septic conditions of the urinary tract generally It is also of special value as a prophylactic against local infection before and after operations on the genito-urinary system.

'Cystazol' is supplied in bottles of 20, 40, 80 and 160 (10 grain) tablets.

'Alopon'

Trade Mark

Powder, Tablets and 'Azoule' Preparations

A Sedative and Analgesic *for general* and pre-operative use, consists of the hydrochlorides of all the alkaloids contained in opium *It presents all the therapeutic constituents* of opium in a soluble and stable form. The mixture of alkaloidal salts, *whilst* exerting a cerebral sedative action practically equal to that of morphine, has a less pronounced depressant action on the respiratory centre. One grain is equivalent to 5 grains of opium or ½ grain of morphine.

In all cases where opium is indicated 'Alopon' may be used with advantage.

"UMBROSE"

Reg. Trade Mark.

(Shadow Meal)

For the preparation of test meals used in the X-Ray Diagnosis of disorders of the Gastro-Intestinal Tract. 'Umbrose' contains 75% of Barium Sulphate and is in the form of an impalpable powder which is treated by a special process in order to secure, when administered, a clear and regular shadow definition.

Prepared in 3 sizes

'Umbrose' No 1 contains 2 oz. $BaSO_4$
'Umbrose' No 2 " 4 oz. "
'Umbrose' No 3 " 6 oz. "

Descriptive Literature and Prices will be forwarded on request to members of the Medical Profession

When in Doubt—?

"Just as in whist in the old days I always led a trump when in doubt, so also when in doubt as to treatment of gastro-intestinal disturbance I have prescribed Dimol for a number of years with the most gratifying results."

London, W. — ——, M.D.
Jan. 8th, 1927.

No dicta of disbelief based on *laboratory experiments* only can upset the potency and non-toxicity of Dimol in clinical experience.

> "It is possible to destroy all bacteria in the fluid contents of the intestinal tract with a duodenal douche of Dimol, but the dosage recommended in the form of tablets or pulverettes (2 to 4 after each meal) is so regulated that the B. coli normally present are not affected, a fact which can only be ascribed to their greater powers of resistance."
>
> *The Lancet*, April 9th, 1921.

By the oral administration of 3 pulverettes thrice daily the *pathogenic streptococci and gas-forming organisms* are so reduced in number that rest is given to the poisoned, distended gut, and recovery established.

SURGERY OF THE SPINAL CORD

We publish in our present issue two communications which demonstrate the remarkable difference in purpose and technique between operations performed in the same topographical area Prof. Oppel, by the skilful removal of a mechanical obstruction in the spinal column, enabled an injured patient to obtain normal movement of the head; while Mr Donald Armour, in his last Lettsomian lecture, concludes a review in which operation on the spinal column is considered mainly as a means of access to lesions of the spinal cord The surgery of the spinal cord and its membranes, with which Mr Armour deals so lucidly, necessarily dates its birth in this its modern form from the rise of aseptic method, but its origins are lost in unmeasured antiquity, and we owe a deep homage to those who laboured so hard to form it in the womb of time Four hundred years ago Ambroise Paré was urging surgeons to operate for the relief of compression of the spinal cord, but 2000 years had then gone by since Hippocrates had discussed the reduction of spinal dislocations and described with unerring accuracy the mechanism of compression in Pott's disease and its independence of angulation Yet so far as is known Cline in 1814 was the first deliberately to remove a depressed vertebral arch, thereby arousing a storm of controversy in the course of which Charles Bell denounced such surgery in no measured terms, whilst Astley Cooper frankly described its opponents as blockheads It is pleasant to think that if the daring of an Englishman aroused the controversy it was the skill of a Scotsman which laid it In 1883 William Macewen operated upon a case of complete paraplegia due to Pott's disease with brilliant success, following this up with equal success in a similar case due to a fracture-dislocation In 1887 the diagnostic skill of Gowers and the manipulative dexterity of Horsley combined in the successful removal of a tumour compressing the fourth dorsal segment of the cord and opened up a new epoch in neurological surgery Methods of access to the cord having now become a matter of established surgical routine, recent effort has been directed to greater accuracy in the diagnosis and localisation of organic lesions of the cord It is known that very slight injury to the arachnoid will lead to the development of adhesions in the subarachnoid space and to a block more or less complete in the circulation of the cerebro spinal fluid The diagnosis of a spinal lesion thus resolves itself into two questions: first, the evidence of a block, secondly, its precise localisation

A block in the cerebro spinal circulation leads to the stagnation of the fluid below it and to the congestion of the meninges, with the very remarkable result that the composition of the fluid is entirely changed Instead of a minute trace of protein it may now contain as much as 2 per cent, whilst in addition it may absorb from the congested vessels altered blood and fibrinogen Thus an increase in the amount of protein, the presence of a yellow pigment, and occasionally spontaneous clotting will establish beyond doubt the presence of an organic block, and this invaluable information may be gained with no greater risk or inconvenience than is involved in a lumbar puncture By the introduction of lipiodol into the spinal theca it is possible in a large number of instances to give visual demonstration on an X ray film of the site of the obstruction. There are, however, considerable difficulties in the interpretation of the results, there are many possible fallacies, and there is undoubtedly some reason in a hesitation to introduce into immediate contact with the spinal cord a foreign substance which remains unabsorbed for a very long period Moreover, modern methods of neurological analysis enable an accurate localisation to be made by purely clinical methods in 98 per cent of the cases, so that there is no real necessity in general for such artificial aids In exceptional cases, however, where the existence of a block has been established, lipiodol does furnish a definite aid in its localisation

The relief of intractable pain is one of the most serious problems of medicine, and towards its solution by surgical means an immense amount of laborious research has been devoted in recent years The splendid work of O Förster on division of the posterior roots has fully justified the association of that operation with his name, but it is of interest to notice that the operation was carried out for the first time by W H Bennett in 1888 In the relief of pain where nerves are involved in malignant growth or in scar tissue the operation has met with great success, but its application to the severe lightning pains of tabes has been disappointing More subtle and more daring is the surgical division of the anterolateral tract of the spinal cord, proposed by W G Spiller, and first carried out by E Martin in America There is in surgery no more elegant application of fine anatomical detail to the treatment of disease The operation itself is of the most delicate order, and its results have been on the whole very successful In 1915 H S Souttar at the West London Hospital applied the method to the relief of gastric crises of great severity in tabes, with immediate and permanent success The operation has since been performed extensively by C H Frazier, M M Peet, and other surgeons, who have fully established the soundness of the procedure

REFLECTIONS ON THE HUME-SPRY CASE

Entirely favourable though it was, the verdict for the defendants in the Hume-Spry case cannot compensate them for the annoyance and anxiety of 15 days actual litigation, for the many weeks of preparing to resist the allegations now shown to have been without foundation, and for the prolonged interruption of their daily work Nor can judgment with costs repay them the expense of the proceedings So long as the discharge of professional responsibilities under the Lunacy Act can thus be rewarded with a heavy loss in time and money, the present state of the law cannot be regarded with equanimity The Royal Commission on Lunacy, in the report issued last July, recommended that a plaintiff should be obliged to discharge the onus of proving bad faith or negligence on the part of the certifying doctor instead of the burden being placed—as at present, in spite of the apparent intention of Section 330 of the Lunacy Act, it sometimes seems to be—upon the doctor to prove positively his own good faith and reasonable care This is no great change, but, for what it is worth, it should be made at once with the addition of all possible safeguards for the medical profession against the indiscriminate institution of civil proceedings It will doubtless be said that the Parliamentary time-table will not allow the introduction of fresh legislation, but there is no reason why a draft Bill should not be prepared and circulated forthwith. While any such legislation is under consideration, the principle of the Public Authorities Protection Act must be strengthened rather than weakened; for a busy medical practitioner is at a serious disadvantage if suddenly called upon to meet allegations about a patient whom he has certified many months before, and it is unfair to prejudice his defence by challenging his recollection upon details which he has had time to forget It must be borne in mind, too, that the machinery of reception orders imposes upon the medical profession duties of an exceptional kind

The evidence of lunacy given by a medical certificate that a person is of unsound mind and requires detention under care and treatment resembles the evidence in no other kind of judicial proceedings. If the matter were conducted in the normal judicial fashion, three rules would apply which the nature of the proceedings excludes First, the person whose mental condition is being investigated would be entitled to have a categorical statement of the matters alleged to impeach his sanity and he would be entitled to make a specific reply, secondly, all hearsay statements would be shut out; and, thirdly, the proceedings would take place in public A fourth rule might then follow—namely, that the doctor upon whose evidence the judicial authority's decision will depend would be entitled to complete privilege and would be protected from legal consequences like any other expert witness before any other judicial tribunal. The contents of the medical certificate are understood to be privileged in the sense that a libel action cannot be founded upon them, but the extent of the privilege should not thus be limited. In no other form of judicial inquiry are expert witnesses liable to be held legally responsible if a party afterwards objects to the consequences of the tribunal's decision The public probably does not realise that the medical certificates are by no means automatic in the obtaining of a reception order. The Lunacy Act requires that the certificates shall be considered by a judicial authority who for this purpose has all his normal jurisdiction to administer oaths and summon witnesses The judicial authority has a statutory duty to consider the evidence, to decide whether he shall personally see and examine the alleged lunatic or not, and to satisfy himself whether a reception order may be made forthwith or whether further inquiry is necessary If he makes the order, the alleged lunatic has afterwards all the safeguards furnished by periodical examination and by the enlightened administrative measures of the Board of Control. In the debate on lunacy recently initiated by Earl RUSSELL in the House of Lords, good reason was given for believing that the supervision of the Board of Control (composed of expert medical and legal members) is a more valuable check upon the certifying doctors' certificates than is the inquiry conducted by the judicial authority before the order is signed. It may be so, but while the judicial authority is retained for the purpose of examining the evidence and of signing the reception order if satisfied by the evidence, the decision of the judicial authority should be final unless it is overruled on appeal, in any event it should not be legally possible to go behind the judicial decision and attack the witnesses unless the latter have been guilty of perjury, subornation, or criminal conspiracy.

Meanwhile, since he is unprotected, the doctor who signs a certificate must take care not to expose himself to attack He would be well advised to make a preliminary draft of the statement of facts upon which his opinion is formed, and to go through it in the light of possible cross-examination in a court of law in future years He should pigeon-hole any notes he has made of the case, and he should be more careful than ever to study the marginal instructions upon the certificate form, and to remember that the Act requires him to distinguish between facts observed by himself and facts communicated by others, Parliament having forbidden a reception order to be made upon a certificate founded only upon facts communicated by others He will not need to be reminded that he will encounter prejudice on the part of persons who suspect that doctors exist to obstruct the liberty of the individual and to segregate in strict confinement all potential Shakespeares, Isaac Newtons, and Beethovens He will find others who hold the primitive belief that to treat a lunatic is an interference with an all-wise Providence Finally, he may find that his worst troubles come from within his own profession Cynical laymen have been heard to remark that, however high the reputation of a medical practitioner, however long his experience and however great his care, some ingenious member of the same calling can always be found to come into court and accuse him of negligence In the HUME SPRY case, the cynics have observed, an expert witness was called for the plaintiff who, seeing Mr HUME-SPRY apparently for the first time in December, 1925 (more than two and a half years after the date of his certification) was prepared to state with confidence in the witness-box that he could find no evidence of the plaintiff being now, or having ever been, insane, that he was not insane at the time when he was certified, and that he should never have been certified. Unquestionably if one medical practitioner thinks that another has improperly led a magistrate to confine a sane man in a lunatic asylum, he must say so when asked in a court of law, truth must not be sacrificed to professional esprit de corps But the jury doubtless remembered the old proverb that an ounce of fact is worth a ton of theory, it was the facts which were fatal to the plaintiff's claim

HEART DISEASE AND PREGNANCY

DIFFICULT decisions often have to be made when a woman with heart disease becomes pregnant, and a recent discussion[1] between physicians and obstetricians at Birmingham serves to show what differences of opinion obscure current teaching There are plenty of opportunities for making mistakes, for even in its more advanced stages heart disease seems to have little inhibitory effect on conception, and troublesome cases—each with its own special problem—are constantly being encountered

Every variety and combination of cardiac lesion may be seen in pregnant women, the commonest being *mitral stenosis, but it is not so much the site as* the extent of the damage and the degree of compensation established which are important, though some lesions imply, of course, a worse prognosis than others There is little evidence of myocardial hypertrophy during normal pregnancy, but there is no doubt that extra work has to be done, and the cardiac output is said to be increased by as much as one-third during the month or two before term This throws extra work on the muscle, the damaged heart is liable to fail, and a certain number of women with advanced heart disease and poor compensation are inevitably destroyed by the strain either of pregnancy or labour. On the other hand, it must be remembered that by no means all the severe cases end like this, and where a lesion is slight and more or less stationary the patient may pass through several pregnancies without obvious ill effect Cases in the intermediate group are those which call for the most careful consideration, for a wrong or a delayed decision may easily have fatal results Hearts in which the damage is of moderate severity often pass through the early months of pregnancy without serious distress, but during the last month or two they show considerable loss of compensation and this means a definite risk of failure, either before or during labour Many of the patients make the efforts of parturition without any great difficulty, and although there is some danger that the heart may fail during the early part of the puerperium, the degree of compensation generally improves Whilst opinion is divided as to whether permanent damage is done to the heart by the added strain of pregnancy, most authorities believe that some of the damage is permanent, and in the majority of households, of course, the care of a new child throws an extra burden on the mother

---

[1] Meeting of the Midland Obstetrical and Gynæcological Society at the Medical Institute, Birmingham, on Feb 8th.

Naturally enough, there is no one line of treatment that is suited to all cases, but some general therapeutic principles are becoming established Any woman who has had failure of compensation apart from pregnancy, or in previous pregnancy, should not be allowed to go to term In these women conception ought to be prevented, but if it should occur, abortion should be induced as early as possible Most operators prefer to use some simple method, and at the Birmingham meeting Mr CHRISTOPHER MARTIN emphasised the ease with which pregnancy may be ended by introducing a solid rubber bougie The only disadvantage of this procedure is that it does not permit of sterilisation, and some obstetricians prefer to remove the uterus, even where the cardiac condition is dangerous In the less severe cases, in which failure of compensation only becomes apparent in the latter part of pregnancy two plans are available Rest in bed and careful medical treatment will often bring about some improvement, and the patient may be allowed to go to term and into labour naturally. The second stage should be shortened as much as possible by operative delivery to avoid the stress of the second stage pains Few now favour the induction of premature labour, as the patient is not saved an appreciable amount of work by this measure The alternative is to perform a Cæsarean section at term or a little before it Here, again the patient should be treated medically for a few weeks previously The operation can conveniently be performed under intrathecal stovaine anæsthesia, although experience shows that ether may be used with safety The great advantage of this method is that the patient can be sterilised at the same time, either by division of the Fallopian tubes or by hysterectomy; the former seems to be the better procedure under the circumstances There is at present a definite tendency to regard Cæsarean section as the correct method of dealing with the more severe cases of heart disease complicated by pregnancy, and on the whole results have been good In accepting this doctrine, however, it must not be forgotten that many lives have been lost owing to delay inspired by the hope of securing a viable child Abortion should be early if the woman is unlikely to get safely to the last month or so of pregnancy, and the cooperation of cardiologist and obstetrician should also be early if the patient is to have the best possible chance. Combined discussion serves a useful purpose, for the obstetrician sees a large number of cases in which no harm results from labour, whilst the physician is likely to be called only to such cases as are in extremis. An exchange of views can do nothing but good, the only danger is that it may be made to excuse a policy of vague anticipation

Ne quid nimis ”

THE LISTER CENTENARY

THE object of keeping centenaries is to focus attention on the comparatively recent past, and the celebrations are only useful if they prevent us from thinking our environment and methods inevitable. The birth of Lord Lister on April 5th, 1827, is being celebrated at Glasgow this week, and in London from April 4th to 6th. The ceremonies are taking many forms, but none of the contributions is likely to be more interesting than the personal reminiscences of those who worked under Lord Lister and knew conditions before he did his work A foretaste of these contributions is given by Sir Hector Cameron in a brief monograph[1] dealing with Lister's work in the wards of the Glasgow Royal Infirmary from 1860 to 1869 The position of surgery before that time was, as he shows, barely conceivable to the present generation "The ultimate fate of every man who had his body wounded, whether by accident or by surgical operation, was a matter of absolute uncertainty" When Lister was appointed to the Infirmary he was given charge of wards Nos 24 and 25 on the ground floor, in the new surgical block which had been opened in the previous year Pyæmia, erysipelas, and hospital gangrene were rife, notwithstanding the newness of the buildings, and about 1868 the mortality became so excessive in ward 23—which was in charge of a colleague—that it had to be closed The trouble was attributed to a foul drain, but it was found that some four feet away from the wards there was a multitude of coffins, containing the remains of those buried during the cholera epidemic of 1849. Yet, in Lister's own words "at the very time at which this shocking discovery was made, I was able to state , that during the previous nine months, in which the antiseptic system had been fairly in operation in my wards, not a single case of pyæmia, erysipelas, or hospital gangrene had occurred in them" The ward in which these marvellous results were obtained is a place which might well have been preserved as a memorial both of the worker and his work, but it has now been destroyed A second centenary contribution[2] sets out with admirable restraint the efforts to preserve it which were made by the Glasgow Lister Memorial Committee, and the reasons why these efforts failed In his introduction, Lord Blythswood points out that the book is published to dissipate any idea that the citizens of Glasgow as a whole were responsible for the demolition of the ward, "the responsibility for this act of vandalism lies at the door of a comparatively small majority of the total number of Managers constituting the Board of the Glasgow Royal Infirmary in the year 1923" The book consists of four sections together with appendices. The first and third are by Mr Ernest Maylard, B S, who contributes an appreciation of Lister and his work, and an account of the efforts for the preservation of the Lister ward The second, by Mr. James A. Morris, architect, gives an excellent account of the Infirmary buildings, whilst the fourth is by Mr L W G Malcolm, conservator of the Wellcome Historical Medical Museum, the authorities of which *have reconstructed a section of the original* ward, the interior furnishing and fitting being those which actually stood in it when Lister began his antiseptic practice

[1] Reminiscences of Lister and of his Work in the Wards of the Glasgow Royal Infirmary 1860–1869 By Sir Hector Clare Cameron C B E, M D, C M, consulting surgeon Glasgow Royal Infirmary Glasgow Jackson, Wylie and Co 1927 Pp 45 1s

[2] Lister and the Lister Ward in the Royal Infirmary of Glasgow A Centenary Contribution Glasgow Jackson, Wylie and Co 1927 Pp 132 12s 6d

The programme of the celebrations in London makes it certain that there will be addresses here as appropriate as these two memorials from Glasgow Though the details have already been published in The Lancet, it is perhaps convenient to set them out again in full —

PROGRAMME OF CELEBRATIONS IN LONDON

Monday, April 4th

11 a m —Reception of Delegates by H M the King at Buckingham Palace

3 p m —King's College Hospital *Addresses on Lister's Personality by Sir Watson Cheyne, F R S, Sir Lenthal Cheatle, and others who served under Lord Lister All old students of the hospital and their friends are invited

8 30 p m —Royal Society of Medicine *Reception by Sir James Berry (the President) and Lady Berry at 1, Wimpole-street, W 1 (Admission by Ticket only Evening Dress) Address at 9 30 P M. by Sir StClair Thomson, entitled " The Centenary of Lister Recollections by one of his House Surgeons "

Tuesday, April 5th

11 30 a m —*Reception of Delegates by the Prime Minister, and Presentation of Addresses, in the Hall of the British Medical Association, Tavistock-square (Morning Dress Academic Dress) Short Discourses by Prof Henri Hartmann (Paris), and Prof Max Ritter von Gruber (Munich), dealing with the effect of Lister's work on surgical and pathological science and practice in their countries

4 p m —Royal College of Surgeons of England, Lincoln's Inn-fields *Conversazione (Morning Dress)

7 30 p m —Merchant Taylors' Company * Dinner at the Company's Hall, 30, Threadneedle-street, E C 4. (Evening Dress with Orders and Decorations)

Wednesday, April 6th

11 15 a m —Westminster Abbey *Memorial Service, with address by the Bishop of Birmingham (Rt Rev E W Barnes, F R S) (Morning Dress Academic Dress) Delegates will have an opportunity of placing wreaths at the Memorial Tablet to Lord Lister in Westminster Abbey

3 p m —*Discourses in the Robert Barnes Hall of the oyal Society of Medicine, Wimpole-street, W 1, by Sir harles Sherrington, O M , F R S , Prof W Bulloch, F R S , and Sir Berkeley Moynihan, P R C S , on Lister as Physiologist, Bacteriologist and Surgeon (Morning Dress)

9 p m —Royal Society *Conversazione at the Society's rooms in Burlington House (Evening Dress with Orders and Decorations)

Ladies will be admitted to the ceremonies marked *

THE HÆMOLYTIC AGENT IN ADDISONIAN ANÆMIA

It is now very generally agreed that achlorhydria is one of the few practically constant features in pernicious or Addisonian anæmia, and a large number *of observers believe that a similar gastric condition* occurs in subacute combined degeneration of the spinal cord An increasing body of opinion accepting this view ascribes the severe and progressive anæmia of both diseases to hæmolysis resulting from bacterial infection of the intestine, this infection being secondary to loss of the protection normally provided by the acid gastric juice Attempts to pass from this hypothesis to the actual demonstration of a specific hæmolytic agent present in the small intestine of such cases have so far failed It has been shown, with some constancy, that the duodenal contents are less uniformly sterile in cases of achylia gastrica, but the presence of hæmolytic streptococci, though reported in some cases, has been denied in others The whole subject is fully reviewed by Dr F A Knott in the current issue of *Guy's Hospital Reports* (lxxvii , 1, 1927) Working in conjunction with Dr J F Venables and Dr A F Hurst, this observer has been able to make extensive bacteriological observations on 37 cases of Addisonian anæmia In about 90 per cent of these he was able to demonstrate the presence in the intestine of hæmolytic strains of bacteria, but he is careful to point out that the infection was not necessarily from sources above the pylorus, and that in many cases the bacteriological strains were predominantly of the fæcal type, particularly *Bacillus coli hæmolyticus* and Gram-positive anaerobes It is not, as Dr. Knott remarks, necessary to postulate that one and only one organism can be responsible for the hæmolysis so prominent in this disease, and it is quite possible that achlorhydria, by permitting large numbers of living organisms to pass through the stomach into the duodenum, may promote a catarrhal state of the intestinal mucosa which facilitates not only its infection with all kinds of fæcal bacteria but also absorption of whatever toxins these organisms may produce. Dr Knott's personal opinion is that in all these cases invasion occurs both from above and below and that it is essentially the fæcal bacteria which produce the distant changes both in blood and nervous tissues, the relative incidence of damage on the two types of tissue being largely determined by the *predominant type of organism* The essay as a whole is evidence of the keenness with which research is being pursued into the causation of a most baffling and serious disease, and it is further typical of the high standard of work which characterises this and previous numbers of the *Guy's Hospital Reports*

VENTILATION

The so-called all-electric house, which is civilisation's latest attempt to save labour and secure comfort, has introduced problems of ventilation which have not yet been generally recognised In ordinary houses there are chimneys and flues which allow the escape of overheated and vitiated air, but the occupants of an all-electric house, unless special provision is made, must always be taking steps to keep the air fresh Though open windows are in fashion, the conditions and simpler tests for successful ventilation are not subjects of common information This bids fair to be changed by suitable instruction in schools The ideal is that air should be reasonably free from smoke, dust, microbes, and odour; it should not overheat nor chill the body, and it should be neither too dry nor too moist To make sure of all these conditions requires rather complicated tests, but it is quite easy for teachers and scholars to take readings from a dry-bulb thermometer every few hours and adjust their windows accordingly A recent book by Dr Thomas D. Wood and Miss E M Hendriksen,[1] shows that in many schools in the United States the keeping of records is part of the daily routine They describe two inexpensive systems of window-ventilation which have lately been found successful They are called respectively the Watt and the Wheeler system In the Watt system the windows are opened at the top, the blinds being placed lower down so that they do not blow about or interfere with the entrance of the air , in some cases the blinds are *in two halves, the top half to* pull up and the bottom half to pull down In the Wheeler system the air enters at the bottom of the window, but is deflected upwards In both systems the exhaust ducts leading away impure air are situated at some distance from the windows, and flags are placed at the openings to see that the current is passing in the right direction The size of the openings is regulated according to the temperature in the room, heat being supplied by radiators Such an arrangement is simple to work and only depends on the presence of a person with an elementary knowledge of ventilation Many expensive systems prove useless in practice for want of this knowledge, but it is easily acquired In Great Britain the optimum temperature indoors is about 60° F , in America it is nearer 64–68° because in winter the air there is drier than in England owing to the cold out of doors. If the air is dry a higher temperature is necessary for comfort. In this country the air in houses rarely becomes excessively dry, for the indoor relative humidity is usually between 40–60. In America, however, it may fall as low as 20, and special methods for moistening the air are being introduced. By valve attached to the radiator supply pipe steam may be passed into the room until the windows show moisture on the panes; this steaming may be carried out in schools both before and after the children occupy the class-rooms. In small houses in America it is advised that pans of water should be placed on each radiator so that at least half a gallon of water daily evaporates into a room of average size. In England, however, this problem hardly arises. When people complain of dryness of rooms, the real trouble is often a leak which permits the escape of fumes from radiators or gas or coal fires. In a house without chimneys it is particularly essential to see that a suitable exit is provided for the products of combustion, as was cogently pointed out in our columns not long ago by Dr. J. S. Owens (THE LANCET, March 5th, p. 514). Laying stress on the dangers of the portable flueless heater as used in living rooms and bedrooms, he laid down the principle that "the heating and ventilation of houses should be inseparable, and a method of heating which does not in itself produce a ventilating effect should be looked on with suspicion." At the present time it is doubtful whether this suspicion is sufficiently widespread.

THROMBOSIS OF VEINS

IN his article on phlebitis of the lower limbs and abdominal wall, which we print on another page, Dr. W. Bain remarks on the scant attention paid to this not uncommon malady in most text-books of medicine, Allbutt's System being a notable exception.[1] Blood-clotting in vivo is a complex process which has been studiously investigated. There are two kinds of thrombi—the coagulative and the agglutinative. The latter are due to agglutination of the red cells and are quite different from those due to coagulation. They are found chiefly in the capillaries, but may occur in veins, and are encountered in infective diseases, such as enteric and pneumonia, and may account for the transient congestions of influenza. The substances that produce coagulation of the blood are fibrinogen, thrombin, and calcium salts. The two theories regarding the method of production agree in this, that fibrin is derived from fibrinogen. The points in dispute are in regard to the origin of thrombin and the mode of action of the calcium ions and the thromboplastic substances. According to P. O. Morawitz,[2] the thrombin exists in living blood in an inactive state called prothrombin, which becomes converted into thrombin by the simultaneous action on it of soluble calcium salts, and of a thromboplastic substance furnished by the tissue cells in general and by the cellular elements of the blood-platelets and leucocytes. This substance acts, therefore, as a kinase and is called thrombokinase. The fundamental fact of this theory is that kinase is necessary for the union of calcium with prothrombin, but W. H. Howell[3] declares that prothrombin may be converted into thrombin by the action of calcium alone. Prothrombin is probably derived from the blood-platelets or from the leucocytes and thrombokinase is produced either by the blood-platelets, leucocytes, the vessel wall, or from the tissues. According to Mellanby, the testis is a suitable source to obtain it for experimental purposes. Loucks[4] believes that thrombin loses its activity when deprived of calcium salts, and that active thrombin cannot be prepared from calcium-free serum or fibrin. G. H. Whipple[5] regards the delay in clotting of the blood in diseases of the liver with jaundice as due to an excess of antithrombin in the blood, but Howell suggests that the prothrombin may be rendered inactive by an excess of heparin. Heparin, which is derived from the liver and other organs, acts by neutralising prothrombin and so preventing coagulation. Cephalin is antagonistic to heparin and antithrombin. Such in brief is the present view of the mechanism of clotting. In the living body a thrombus begins by the deposition on the wall of the vein of a minute pearly translucent mass of blood-platelets. The platelets are clustered together forming an irregular sticky substance, catching the passing leucocytes, and they, and perhaps the platelets, appear to liberate thromboplastic material so that filaments of fibrin spread out and entangle numbers of red cells. The thrombus tends to grow by accretion, so that parts of it show differences in colour. The clinical bearing of these facts is the subject of Dr. Bain's observations.

DRUG-TAKING IN SOUTH AMERICA

THE war is held responsible for the increase in drug-taking during the last 10 years even in countries that remained neutral. The increase was indeed noticeable before 1914, but that it received a great impetus from the abnormal psychological conditions engendered by the war, even in remote countries such as the Argentine, is argued by Dr. Gregorio Bermann,[6] professor of medicine in Cordoba. He states that in Cordoba, a town of 200,000 inhabitants, as also in Buenos Aires, the evil is rampant and widespread among the upper classes. It has become a fashionable vice, widely diffused by the "patotas" or social clubs, which has been calculated to affect in these towns two and a half to three per thousand of the population. The effect of severe legislation was, in Cordoba at least, largely rendered nugatory by the high position of the offenders whose relations used their influence on the judiciary to avoid scandals. Nevertheless, in Dr. Bermann's opinion, there has recently been a considerable diminution; the open trafficking and solicitation no longer exists, though still prevalent enough in the under-world of prostitution and debauchery where this vice finds its natural habitat. As to whether the individual affected is to be regarded as a criminal or an invalid, Dr. Bermann takes up a rational position midway between the two extremes; he is wholly opposed to the elimination of moral responsibility in these cases, whilst admitting that the confirmed drug-taker has to be treated as a sick person. He discusses at length the origin, associations, symptoms (physical and moral), and the consequences of the various drug addictions, special attention being given to the abnormal mental states produced by them, and the medico-legal problems which arise. His own experience seems to have been largely with cocaine, which he regards as the typical vice of rich decadents and closely connected with prostitution and alcoholism; but all the various phases of drug addiction are illustrated by numerous interesting cases drawn from the author's own practice. As remedial measures he advocates the international limitation of the cultivation and manufacture of opium and coca, and as national measures the following: (1) The institution of "ambulatorios," presumably out-patient clinics for the assistance of neuropaths. (2) Combined action on the part of the authorities and the League of Mental Hygiene against alcohol and other drugs. (3) Education of the professional classes concerned. (4) A strict watch over contraband. He would make the unwarranted keeping of such drugs illegal and close offending pharmacies. Lastly he would provide an asylum colony for habitual drug-takers and deprive them of civil rights Dr. Bermann interpolates a few notes on drug-taking in the United States, where he estimates it to be at least three times as prevalent as in Cordoba The worst period seems to have been about 1919–20, when its prevalence in the United States led the authorities in two or three States to set up special hospitals and special administrations to deal with it In common with some American writers, he does not consider that prohibition was the cause of so much increase in the United States as many believe No Englishman can read the strictures passed on this country by the author (pp 44–5, 338–9) without pain and a feeling that it is impossible morally to justify the policy pursued by England as regards the opium traffic in China, India, and Burmah for the last century. It would be difficult to persuade even an unprejudiced foreigner that in this matter the claims of morality and health had not been subordinated to those of revenue, but we may at least be thankful that this year, 1927, will see the beginning of the end of opium trading in India and that in ten years' time the Government production of opium, except for purely medical purposes, will have ceased entirely Dr Bermann is perfectly correct in stating that the primary factor in the suppression of the evil is the control of the original sources of production Once produced, all the energies of perverted human nature are called in to effect its distribution

HANDLING OF WOUNDED IN AMPHIBIOUS WARFARE.

IN the *Military Surgeon* for March two United States medical officers, one from the Navy, one from the Army, discuss the Medical Tactics of Joint Army and Navy Operations, in relation particularly to an opposed landing on a hostile coast, the landing at Gallipoli being their special text They point out that an army cannot itself deal properly with the casualties incurred in landing operations until its hospitals are landed, and that will not be until the landing force has made some headway Meantime the wounded must be sent back to the transports which have been prepared for them This preparation involves close touch between the commander-in-chief and his senior medical officer, who must not be misled by hopeful forecasts as to the probable number of wounded, for there may well be 50 per cent When troops are first landing, only the regimental medical personnel will be wanted ashore, when some advance has been made, field ambulances without transport will be the next need, then casualty clearing stations after them, last of all base hospitals, whose stores and staff may meanwhile be utilised afloat for the early care of the wounded brought back to the transports Landings may take place at several beaches, and transports appropriate to each will be preparing to be hospitals as soon as they have discharged their troops Casualties will be brought back in boats that have landed troops, provided (it is added hopefully) the landing of troops is not thus delayed A naval medical officer, as embarkation officer for wounded, will be on the staff of each naval beachmaster, he will know what transports are available to take what casualties (one detailed for gas cases, one for walking wounded not to be evacuated, and so on), and there will be another naval medical officer with the military officer commanding the landing to give to these naval medical embarkation officers what further or temporary orders become necessary Meantime the military medical officers who can at the moment be spared (as above) will have been assigned to the transports denoted, with orderlies and stores as required. It is thought by the writers that casualties thus embarked in transports will for the future come officially under the Navy until disembarked, though the Army will give all possible help The scheme of which this is a very brief summary is worked out in minute detail, and will afford material for important discussion A semi-official note at the end of the article expresses certain views of the U S Army Medical Department, supposed to be in some degree at variance with those of the sea service That army envisages two sorts of hospital ship one to be used exclusively for treatment of the sick, reported to Geneva by name, painted white and green, carrying the Red Cross, and enjoying immunity from attack or capture; the other known as the hospital carriers or ambulance transports, which may be equally privileged if reported before a war, but which claims immunity only while employed in transporting patients Alternatively, these ships might become immune by transporting exclusively medical personnel and stores on the outward voyage

E 107

AT a recent meeting of the Berlin Medical Association, described in the *Manchester Guardian* for March 25th, clinical reports were presented on the action of a new anæsthetic which has been invented by chemists of the German Dyestuffs Federation This compound, whose nature is not divulged, is called E 107, and has been tried by seven independent observers in some hundreds of cases A small quantity is passed into the rectum in a clyster while the patient remains in bed in the ward, and within seven or eight minutes he is ready for operation, he is sufficiently relaxed, breathing is as quiet as in sleep, and the induction has been acomplished without causing nervousness, struggling, or undesirable reflex actions According to the reported claims, recovery from the effects of administration is unattended by vomiting or any untoward symptom, and the new anæsthetic is regarded as suitable both for the old and feeble, it has been tried successfully for the production of twilight sleep Were nothing else recorded, it might appear that E 107 is an almost ideal means of producing anæsthesia, but unfortunately it caused in some patients a certain amount of intestinal irritation, whilst in others cyanosis supervened and artificial respiration became necessary Prof Unger, however, in his whole series of 300 cases, is said to have noted no irritation of the intestine, a fact which he attributes to having made sure that the samples of the drug had not deteriorated before they were given And it is suggested that respiratory depression only occurs in a certain type of patient From the accounts given in English newspapers it is not clear what type this may be, but the German observers are quoted as saying *that it may be detected* before induction of anæsthesia, so that no one need be given E 107 who is likely to react to it badly Bearing in mind the natural tendency to exaggerate the advantages of a new preparation, it nevertheless seems likely that the drug will be useful The uncertainty of absorption from the intestine must be reckoned with, and it has to be remembered that no injection—whether into skin, muscle, vein, or intestine *—can give the anæsthetist the constant* control of dosage which is possible when administration is by way of the lung A larger margin of safety is therefore required for drugs not given by the respiratory tract Given such a margin, however, it is an advantage to avoid the bronchial tubes and *alveoli* because the chance of post operative pneumonia is thereby lessened

CANCER OF THE CERVIX IN PREGNANCY.

IN a paper read before the Medical Society of the District of Columbia, Dr Joseph T Mundell,[1] of Washington, quoted the following statistics to show that carcinoma of the cervix is rarely seen in association with pregnancy. Sawey in 1899 estimated its occurrence as once in every 2000 pregnancies B C Hirst in 1923, as the result of a questionnaire sent to a number of obstetricians in the United States, found that in a *total* of 299,621 pregnancies there were 24 cases of cancer of the cervix, or 1 in every 12,484 pregnancies The highest and lowest ratios were as follows. Asa B. Davis reported 137,966 pregnancies with five cases of cancer, or 1 in 27,599, while Mussey of the Mayo Clinic reported eight cases among 3500 pregnancies in the course of 13 years, or 1 in 437. In most instances cancer preceded pregnancy, but in a few it developed during pregnancy. The differentiation, however, was without practical significance Opinions are divided as to what effect pregnancy has upon cancer While some authorities maintain that the increase in the blood and lymphatic supply associated with pregnancy tends to favour the growth of cancer, others claim that the great increase in the connective tissue of the pregnant uterus acts as a barrier to malignant aggression On the whole the trend of opinion amongst recent observers seems to be that pregnancy has a tendency to retard the growth of cancer. It is generally accepted, however, that after the termination of pregnancy the growth of cancer is very rapid. As regards treatment an early operable case of cancer of the cervix complicating pregnancy in the third month calls for immediate hysterectomy In more advanced cases this operation is futile. Treatment with radium endangers the fœtus, for although many cases are on record in which it has been used during pregnancy without deleterious effects, it has, nevertheless, been shown repeatedly that radium may do harm both to experimental animals and to the human subject Perhaps, therefore, the most satisfactory treatment to adopt in advanced cases is cauterisation of the cervix Dr Mundell records the case of a well-developed woman, aged 25, whom he treated for rapidly growing cancer of the cervix by applications of radium He was unaware that she was pregnant and had attributed the increased size of the uterus to the advancing growth of the cancer. After six applications of radium a three months' fœtus was expelled, and the woman died seven months afterwards.

SYNTHETIC THYROXIN

IT is significant that the two awards made at the nnual general meeting of the Chemical Society on Iarch 24th should have been to workers on the onstitution of natural products of therapeutic nterest Prof R Robinson's work on alkaloids earned or him the Longstaff Medal, whilst the Harrison ward went to C R Harington for brilliant and apidly executed research on the active principle f the thyroid gland Kendall, working in the United States, had expressed the view that thyroxin contained he 4 : 5 · 6 tri-iodo 2 : 4 . 5 · 6 tetrahydroindol ucleus and gave an empirical formula $C_{11}H_{10}O_3NI_3$ Harington, believing the properties of thyroxin were more satisfactorily accounted for by ascribing to it a different structure, synthesised 3′ 4′ : 5′ tri-iodo phenylpyrrolidine carboxylic acid, with the disappointing result that the product had not the physiological properties of thyroxin[1] By attacking the natural substance itself he managed to obtain a 0 12 per cent yield from the thyroid, many times greater than Kendall had obtained, and found that the empirical formula was $C_{15}H_{11}O_4NI_4$ The percentage composition of this substance is not very different from that proper to Kendall's formula which was based on rather slender evidence. That Harington's own formula was correct was shown by a study of the constitution of the substance which he found to be an iodine derivative of the parahydroxyphenyl-ether of tyrosine. Harington proceeded to deiodise the natural principle and show its identity with this tyrosine derivative. Finally and very recently a reasoned series of reactions based on the constitution of known natural iodo-derivatives of tyrosine led to the synthesis of β [3 . 5 di-iodo-4 (3′ 5′ di-iodo 4′ hydroxyphenoxy) phenyl] α amino-propionic acid which is indistinguishable chemically and physiologically from natural thyroxin[2] Thyroxin contains about 65 per cent of iodine, a fact so outstanding that as recently as 1918 the late Sir William Bayliss wrote "The most interesting fact, chemically, with regard to the thyroid is the high content in iodine, which appears to be present in a complex organic iodine compound united with a protein That this is the active principle is shown by the fact that the effect of thyroid substance, which is active even when taken by the mouth, is in proportion to its iodine content"

It is highly creditable that a British bio-chemist should have so advanced our knowledge of this important substance While it is unlikely that either natural or synthetic thyroxin will ever become a very cheap drug, the fact that an active artificial product can be prepared ensures the supply, in any desired quantity, of a substance of definite activity. An achievement of this kind is of more value to humanity than the discovery of even the most beautiful of new dyes, but it must not be forgotten that it is only the profound knowledge of the possibilities of complex molecule-building and molecule-analysis which have been developed by "juggling with benzene rings" and other organic complexes that has developed the extraordinary chemical insight and technique that makes the synthesis of such bodies as thyroxin possible

THE STORY OF THE RED CROSS

MANY people charitably inclined and anxious to be of service to their fellows, either by deed or alms, have the most hazy ideas as to what the Red Cross Society is and what it does These will find the necessary enlightenment in Sir James Magill's very readable account of the development of the Society[1] The practical founder of the Society was Mr Henri Dunant, a Swiss gentleman who happened to be present in a private capacity at the Battle of Solferino in June, 1859, when French and Italians attacked Austrians who held a very strong position Three hundred thousand men were engaged and the mass of wounded was so great that the existing medical services were totally inadequate to deal with them In 1862 Mr. Dunant published a book called "Un Souvenir de Solferino," the outcome of which was an International Conference held at Geneva From this Conference sprang the Geneva Convention of 1864, which laid down the lines of treatment of the sick and wounded in war and of persons attending them—i e, they were to be considered neutrals—that are followed to-day. How the Society grew in these islands, and how branches were founded throughout the world is detailed by Sir James Magill The British Red Cross Society obtained a charter under King Edward VII in 1908. A long and most interesting account of its activities and those of the Red Cross organisations of the Dominions, Colonies, Allies, and Neutral Powers during the Great War is given in Chapter IV., and it is worthy of note that in October, 1914, it was decided that the British Red Cross Society and the Order of St John of Jerusalem should pool their resources and enter upon a working agreement with a view to economy and efficiency "during the existing war and thereafter if the circumstances permit and require it" In 1923 the Central Joint V.A.D. Council issued a new scheme for V.A.D.'s, and certain details for this were laid down in Paragraph 17 of the General Regulations (July, 1925); but it is too soon at present to form any trustworthy estimate of how the scheme is working Sir James Magill's book should be read by everyone interested in the work of the Red Cross and its efforts on behalf of all sections of the community in need of its ministration.

THE report for 1925 on the Health of the Army reaches us less than 15 months after the close of the period to which it relates, which is evidence that post-war delay is being overcome The officers' death-rate increased from 3 93 (in the previous year) to 4 44 per 1000, that from injuries dropped from 1 85 to 1 42, but that from "diseases of the digestive system, except liver and tonsillitis" rose from 0 39 to 0 91 The death-rate of other ranks was 2 35 (previous year 2 80), from injuries 0 62 (0 90), from pneumonia 0 33 in both years, from digestive diseases 0 25 (0 21), and from influenza only 0 02 (0 09) The striking feature of the year is the increase in gastric and duodenal ulcer recently noticed, last year there were 25 and 29 cases, but this year 41 and 53. Appendicitis is also on the increase We shall return to the consideration of this Report

THE HARVEY MEMORIAL AT HEMPSTEAD CHURCH

Two years ago the Royal College of Physicians of London took the initiative in an appeal for the rebuilding of the tower of Hempstead Church, Essex, where lies the body of William Harvey A marble sarcophagus had been provided by the College in 1883 just after the old battlemented tower with its fire bells had fallen to the ground, and the appeal was directed to medical men of all nations to erect a tangible memorial of one of the great men of their profession The probable cost was estimated at £5000, of which about one-tenth had already been contributed locally

At a meeting of the Committee of the Restoration Fund held at the College on March 9th, the following report was received —

Receipts	£	s	d
Donations received	431	10	6
Interest on Investments, &c	32	2	8
	£463	13	2
Expenditure			
Expenses of Appeal	59	14	10
Purchase of £360 5 per cent. War Stock	363	6	9
Balance in hand and at Bank	41	1	7
	£463	13	2

This is in addition to the sum of £515 collected locally previous to the appeal, and invested in 5 per cent War Stock It was resolved to keep the fund open in the hope of receiving sufficient further support to commence the rebuilding of the tower Subscriptions may be sent to Dr Sidney Phillips, Joint Hon Sec of the Fund, Royal College of Physicians of London, Pall Mall East, S W 1.

A SCHEME OF DISTRICT NURSING —At the College of Nursing on March 24th a number of district nurses met the Directors of the Mutual Property Insurance Company, Ltd , to discuss the nursing service recently organised by the company Miss Dorsey, R N , of the Nursing Division, League of Red Cross Societies, briefly described from the chair her experience when coöperating with the Metropolitan Life Insurance Company of New York. In 17 years the nursing service of this Company paid more than 27,000,000 visits, 3,000,000 in 1926 , during this time the mortality-rate of the population fell by one-half, and that of typhoid by 82 per cent. Miss Dorsey urged district nursing associations to coöperate with the M P Insurance Company Dr J A H Brincker spoke of the new arrangement between public health authorities and the Metropolitan Asylums Board, whereby, in a measles epidemic, preference in admission to hospital would be given to severe measles over mild scarlet fever, and thus a new field for service would be opened to the district nurse In the ensuing discussion an almost unanimous desire was expressed for the development of public health nursing in this country on general rather than on special lines Miss Wilmshurst, S R N , superintendent of the Metropolitan District Nursing Association, spoke of the preventive side of district nursing and the opportunities it affords for health teaching in the home

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXVII —THE TREATMENT OF CHRONIC APPENDICITIS

THE term "chronic appenditicis" in its widest sense includes all those cases which are not acute, and therefore includes the interval appendix In cases which have been tided over an acute attack by means of expectant treatment, the appendix should be removed after infection has subsided and before recurrence is likely Commonly the time selected is about three months after convalescence from the acute attack ; a longer interval subjects the patient to the risk of another acute attack, especially in young patients. It is estimated that 80 per cent of patients of all ages relapse within two years after an initial attack of acute appendicitis without appendicectomy In these cases a definite diagnosis has presumably been made, and therefore, unless any other lesion is suspected, a gridiron incision gives suitable exposure. As a rule surprisingly little pathological change is found in an appendix which was known to have been acutely inflamed or even the cause of an abscess a few months previously. A few limited adhesions, a stricture or a fibrotic tip are commonly the only legacies of the acute attack

Chronic appendicitis may present as one of two more or less definite clinical entities—i e , the intermittent, and the chronic dyspeptic type

The Intermittent Type

The intermittent type is characterised by recurrent attacks of pain, sometimes colicky in nature, which originate in the neighbourhood of the epigastrium or umbilicus, and are later referred to the appendicular region Vomiting may occur, but is not a marked feature After an interval varying from a few hours to a few days the symptoms abate, leaving a temporary local soreness in their wake On examination some deep tenderness can usually be elicited in the lower right quadrant, and occasionally a thickened or concretion-containing appendix can be palpated through a thin abdominal wall

On removal the appendix is found to contain a concretion or possess a stricture, the symptoms presumably being due to spasmodic efforts of the organ to overcome the resultant obstruction

The Dyspeptic Type

The dyspeptic type of chronic appendicitis is less definite in its symptomatology, and may mimic almost any chronic abdominal condition Generalised abdominal discomfort is more or less constant and may be aggravated by exercise Hæmatemesis and even melæna may occur, but the periodic remissions of symptoms so characteristic of gastric or duodenal ulcer are not marked Symptoms are not relieved by recumbency or pregnancy, which fact may assist in the differential diagnosis of visceroptosis Neurosis is a commonly associated condition, being partly due to prolonged ill-health, and sometimes aggravated by injudicious treatment The discomfort associated with renal conditions is usually limited to the side of the lesion, whereas, although the tenderness of chronic appendicitis is commonly localised to the right iliac fossa, the actual pain is referred more centrally Suspicions of pelvic disease may be aroused by the history of the case, pain is commonly referred to the lower part of the back, and routine examination usually reveals the cause of the trouble

On removal this type of appendix may show generalised or local fibrosis, especially of the tip In other cases the organ may be transformed into a mucocele, or even an empyema

Differential Diagnosis.

The various conditions which must be borne in mind in the differential diagnosis of chronic appendicitis may be summarised as follows:—

Thorax.—Prodromal dyspepsia of phthisis.

Upper abdomen.—Gastric and duodenal ulcers, gall-stones, chronic pancreatitis.

Central abdomen.—Visceroptosis, tuberculous or chronic simple adenitis, colitis.

Pelvis.—Pyosalpinx.

Genito-urinary.—Renal calculus, chronic pyelitis.

Central nervous system.—Neurasthenia.

It will be seen from this summary how many are the pitfalls waiting to entrap the unwary. The public, and even some practitioners, think that chronic disease of the appendix can be diagnosed with certainty by a single abdominal palpation, but in fact it is not easy to decide whether or not the condition is present. Even when symptoms continue after removal of an apparently normal appendix they are sometimes ascribed to "adhesions," until the real cause of the trouble is discovered or manifests itself later.

Exhaustive examinations and repeated observations are usually necessary, particularly with the dyspeptic type, and even then a tentative diagnosis may only be made by a process of exclusion. The mimicry of chronic gastric ulcer by a diseased appendix has been referred to above, and may even be carried to the length of hyperacidity and hypertonicity. If the organ is diseased, removal will probably relieve the symptoms and may restore physiological balance—i.e., the hyperacidity and hypertonicity associated with appendicular gastralgia may disappear. Similarly, persistent colitis may be maintained by a diseased appendix, and if definite symptoms and disability are present, then laparotomy may be justifiable in order to ascertain the condition of the appendix and to estimate its influence on other abdominal organs.

Much has been written regarding the value of barium meals or enemata in the diagnosis of chronic appendicitis. Distortion or kinking of the appendix, retention of barium after the emptying of the cæcum, and tenderness on palpation have all been mooted as diagnostic of pathological changes. However, much must depend on chance as to whether opaque media enter the appendix, or, having entered, how long the medium will be retained. Moreover, palpation of any appendix which is distended will naturally elicit tenderness. In the experience of most surgeons, radiography is of little value in the diagnosis of chronic appendicitis.

Conservative Treatment.

Having considered the differential diagnosis from other surgical conditions, consideration should be given to teeth, diet, mode and habits of life, particularly with regard to smoking, overwork and lack of exercise. Conservative lines should especially be considered in connexion with neurasthenics and elderly patients, especially females.

Operative Measures.

If improvement is unsatisfactory then operation is seriously considered, particularly under the following circumstances:—

1. Recurrent cases, especially if colic is well marked, as the diagnosis is then usually correct.

2. In children, as prolonged dietetic treatment and restriction of activities are obviously unsuitable. Also the neurotic element can usually be excluded and the risk of acute exacerbations is greater than in adults.

3. When the appendix, if diseased, may be exerting a malign influence on other abdominal organs—e.g., stomach, colon. If in the absence of physical signs, symptomatic treatment does not relieve the patient and no marked neurotic element is present, then the condition of the appendix should be verified.

4. In a few cases, if a family predisposition to acute appendicitis exists, appendicular symptoms may justify appendicectomy, both from the risk of an acute attack, and to relieve the patient of a natural dread of a sudden dangerous illness.

In considering the treatment of chronic appendicitis, appendicectomy is, of course, indicated in all genuine cases.

If, in the event of an error of diagnosis, some other condition is present which is amenable to surgical treatment and may be dealt with through the laparotomy wound, little harm is done, but good exposure must be obtained in order that other lesions may be readily recognised.

With regard to the means of approach, the gridiron incision provides adequate exposure if no other pathological lesion is present. However, complete exposure is impossible through this incision, and the upper abdomen and pelvis are out of reach for surgical procedures. The surgeon who explores the pelvis by means of one finger inserted through a gridiron incision merits, and often obtains, the derision of the gynæcologist.

Battle's incision, which consists in inward displacement of the rectus muscle has nothing to commend it. If prolongation of the incision is necessary, intercostal nerves are seriously jeopardised, and in any case they are likely to be crushed if the vessels which accompany them are injured. Injury to these nerves results in risk of subsequent ventral or inguinal herniæ. Therefore in chronic cases the most suitable incision is undoubtedly the right paramedial, as laparotomy for chronic appendicitis is probably the opportunity of a lifetime to explore the whole abdomen, and it is universally accepted that chronic appendicitis is frequently associated with, and possibly the cause of, such conditions as gastric or duodenal ulceration and gall-stones.

The incision commences at the level of the umbilicus, one inch from midline, and extends downwards for about four inches. The anterior sheath of the rectus muscle is divided and separated inwards until the inner border is exposed. The muscle is then retracted outwards and the posterior sheath of the peritoneum divided, the deep epigastric vessels being ligatured if necessary. The cæcum is withdrawn and the appendix removed. Systematic examination is then made of the abdominal contents, particularly the stomach and duodenum, biliary apparatus and the pelvis. Should other conditions be present which are amenable to surgical treatment, the incision may be prolonged in either direction as far as necessary, the rectus and its nerve supply being safely displaced outwards.

In conclusion, mention must be made of the so-called carcinoma, or the cancroid appendix. The condition occurs most commonly in young adults, and is uncommon, only two cases occurring in 750 consecutive appendicectomies by the writer. It is usually revealed by acute infection superimposed on the chronic condition. On removal the appendix is markedly thickened and may be one inch in diameter. Microscopically the condition is one of spheroidal-celled carcinoma. The condition is relatively innocent, secondary deposits being recorded in only 12 per cent. of cases.

R. J. McNEILL LOVE, M.S. Lond., F.R.C.S. Eng.,
Surgical First Assistant, London Hospital, Emergency Surgeon, Mildmay Mission Hospital.

MIDDLESEX HOSPITAL.—The most important announcement made at the annual meeting, over which Prince Arthur of Connaught presided, was that £100,000 had been given anonymously for the building of a nurses' hostel on a site adjoining the hospital. At present the nurses are housed in five separate buildings. The gift will provide for the first section of the hostel, with about 180 bedrooms, together with refectory and recreation accommodation for the full personnel, ultimately to be lodged in it. It is expected that the rebuilding of the west wing of the hospital will be begun by midsummer.

Special Articles.

BOVINE TUBERCULOSIS AND THE TUBERCULOSIS ORDER, 1925.

BY WILLIAM G SAVAGE, B Sc, M D LOND,
MEDICAL OFFICER OF HEALTH FOR THE COUNTY OF SOMERSET

THE evidence is conclusive that a material proportion of human tuberculosis is of bovine origin, due to the consumption of cows' milk containing living tubercle bacilli Any measures in force for controlling and diminishing the amount of bovine tuberculosis must therefore be of interest and practical concern to those engaged in public health The Tuberculosis Order has been advocated and recommended, not only as a valuable agent for the diminution of bovine tuberculosis, but also as an important means of reducing the dangers from tuberculous milk It is necessary to study with care the actual working of this Order, and to try to ascertain how far it is likely to reduce the danger of milk acting as a vehicle for the conveyance of tuberculosis With this object I have made a careful study of its working in a very large dairy county for the 16 months of its operation to the end of 1926 I have no reason to believe that the procedure in this county differs in any essentials from the practice all over England while in many ways its administration must be regarded as on a high level, as regards the care with which different requirements are carried out

The Theoretical Aims of the Order

It is admittedly impracticable to slaughter all cattle suffering from tuberculosis The Order does aim, however, at reducing infection and so diminishing the amount of tuberculosis It is a development of the method advocated by Prof Ostertag, of Berlin, of the elimination of all "open" cases of tuberculosis from dairy herds In his method this was attained by periodical examinations of the herds by veterinary inspectors, together with bacteriological examination of the mixed milk If tubercle bacilli are found in the , or if suspicious animals are clinically detected, erinary and bacteriological examinations are again de of these animals The animals with "open" erculosis are slaughtered, while the premises are roughly disinfected This complete plan is not followed, but in the words of the circular of the Board of Agriculture—

> "The Order aims at the destruction of every cow suffering from tuberculosis of the udder or giving tuberculous milk and every bovine animal suffering from tuberculous emaciation or suffering from a chronic cough and showing definite clinical signs of tuberculosis"

Three types of tuberculosis are scheduled, i e —

(1) Any cow which is, or appears to be, suffering from tuberculosis of the udder, indurated udder, or other chronic disease of the udder

(2) Any bovine animal which is, or appears to be, suffering from tuberculous emaciation

(3) Any bovine animal which is suffering from a chronic cough and showing definite clinical signs of tuberculosis

These three types may conveniently be called the designated types of tuberculosis The knowledge of these animals administratively is obtained from two sources, i e —

(1) Every person in charge of an animal which may be suffering from one of the designated types of tuberculosis has, without unavoidable delay, to give information of the fact to a police-constable or to an inspector of the local authority.

(2) A veterinary surgeon who, in his private practice, comes across such an animal has to notify it to an inspector of the local authority

The Order provides for examination of these notified animals by a veterinary inspector appointed by the local authority, for their slaughter if considered to be in one of the three designated groups with compensation to the owner according to a definite scale. The local authority referred to is the local authority under the Diseases of Animals Act, 1894

To estimate the efficiency of the Order as an agency to reduce bovine tuberculosis, certain points are obviously of fundamental importance

The Stage at which the Three Specified Classes of Tuberculous Animals are Notified and Destroyed

These cases of advanced tuberculosis are a great danger to the rest of the herd, since they eliminate tubercle bacilli in their expectoration and in their fæces Ostertag's procedure has a definite scientific aim—i e, to detect these animals by the aid of bacteriology and veterinary examinations within a short time of their becoming "open" cases The Tuberculosis Order does not make use of these aids, but relies on a system of notification by owners and veterinary surgeons In this country it is not the practice of farmers and breeders to have systematic veterinary inspection of their bovines, but only to call in a veterinary surgeon when an animal is definitely ill Only a small proportion of animals in the designated classes are likely therefore to be notified in this way Of the 798 animals dealt with to the end of 1926 only 172 were reported by veterinary surgeons, and this number includes those found when inspecting herds containing a notified animal, while 612 were reported by owners, the remaining 14 being otherwise reported In practice the onus of reporting these designated animals is mainly thrown upon the owners The average farmer is very ill-informed in regard to tuberculosis which cases are dangerous, and how it is spread Tuberculosis of the udder is difficult to diagnose except when advanced The owner has not to report emaciation, but only an animal which "appears to be suffering from *tuberculous* emaciation"; he has not to report a chronic cough, but only an animal which is "suffering from a chronic cough *and* showing definite clinical signs of tuberculosis" He is under no obligation to call in veterinary assistance if he suspects, and obviously he can postpone notification until any animal is of no further use to him without the slightest risk of incurring any penalty.

Theoretical considerations suggest, therefore, that the bulk of the animals are only likely to be reported after the condition has existed for a long time, and after the animal has been an active spreader of infection This is amply substantiated when an analysis is made of the returns.

The 798 cases were as follows —

Classed as "advanced" tuberculosis .	496
" " "not advanced" .	284
" " udder tuberculosis (entirely or mainly)	13
No tuberculosis at post-mortem	5

A number of the "advanced" and "not advanced" groups showed udder lesions, and this point is dealt with below, in addition to other lesions of tuberculosis.

Section 9 (4) of the Order defines the conditions to be included as "advanced" tuberculosis. It must be noted that "not advanced" under this Order does not mean what it would do in a medical diagnosis An animal can have extensive and old-standing lesions and still be classed as "not advanced" The following are examples of post-mortem records of cases classified as "not advanced".—

Tuberculosis of the lungs, pharyngeal, mediastinal, and mesenteric glands
" " mesenteric glands intestines, and several joints
" " both lungs and miliary tuberculosis of the liver
" " the intestines and of the bronchial glands
" " the lungs, pleura, and mesenteric glands

It is evident that a good many of the cases included in my summary as "not advanced" belong to the advanced group, and if correctly placed would have sent still higher the percentage of advanced It is perfectly clear from the above figures and a study of the post-mortem returns that a preponderating proportion of the cases are old long-standing cases, most of which have been excreting tubercle bacilli for a long time before their slaughter under the Order A single example may be quoted, and it refers to an animal killed December, 1926—

i e , after the Order had been in operation for nearly 16 months The post-mortem record reads —

> "Generalised tuberculosis tuberculosis of liver, kidney, pleura, intestines, miliary tuberculosis of both lungs, submaxillary, parotid, pulmonary, bronchial and hepatic glands tuberculous No tuberculosis of the udder"

The Extent to which the other Animals are Examined in a Herd found to contain a Positive Notified Case of Open Tuberculosis

The Ministry of Agriculture and Fisheries emphasise the importance of this in Circular Letter No 13 (July, 1925), and point out —

> "Where the report has been received in respect of a particular animal the examination conducted by the veterinary inspector should not be confined to the animal which was the subject of the report, but should be extended to other bovine animals on the premises, and particularly to all milch cows, and the veterinary inspector should make an exhaustive clinical examination of any animal which there is reason to suspect of suffering from tuberculosis of the udder, from tuberculous emaciation, or of giving tuberculous milk".

Such an investigation is obviously of great importance from the preventive standpoint There are three different attitudes One is the wording of the Order itself which is non-committal and leaves it entirely to the veterinary inspector to examine any other animals on the premises which he "considers it desirable to examine" The second is the wholly admirable urge of the Ministry of Agriculture, quoted above, to investigate the other animals for sources of tuberculous infection The third attitude is that of the local authorities administering the Order which, so far as I can ascertain, is generally in the direction of strongly discouraging any detailed examinations of the other animals I have been told by responsible veterinary inspectors in other areas that they have been definitely instructed not to examine the other animals except under special circumstances

In the county under consideration it is evident that only in a quite small minority of cases are the other animals examined This is shown by three sets of facts In the first place, an examination of the actual returns shows that it is quite the exception to examine the other animals, although a place is provided for this information The records are badly kept as regards this point, so exact statistics cannot be given, but even giving the credit to doubtful cases, the total of herds examined is a very small proportion of the whole The usual plan seems to be to ask the farmer if he has any doubtful animals, and to look at these, while in some cases the animals are paraded for the inspector, but clearly this is not in any sense an examination

In the second place the extra fees paid out to veterinary surgeons for these secondary examinations amount to a very small sum during the 16 months, and afford definite evidence of active discouragement

The third fact is the number of cases in which the examination of the other animals has resulted in the detection of an animal suffering from one of the designated types of tuberculosis During the whole 16 months only 24 such positive cases were reported Some of these were after an examination of all the bovines, or at least of all the cows, but in a good many cases they were individual suspected animals brought forward or picked out without an examination of the whole herd The primary animal causing the veterinary inspector to visit was either an animal suffering from emaciation or chronic cough, none from tuberculosis of the udder Most were single cases, but three were on one farm, and two were reported from each of two farms—i e , they were from 20 herds These 24 animals were —

8 cases of advanced tuberculosis } with no mention of udder
7 ,, ,, not advanced ,, } involvement
5 ,, ,, advanced ,, with definite udder tuberculosis
4 ,, ,, udder tuberculosis (alone or mainly)

It is certain that if more herds had been systematically examined many more affected animals would have been discovered One example of what happens may be quoted An emaciated animal was slaughtered, November, 1926, and showed post mortem very advanced tuberculosis, the following being mentioned as tuberculous—both lungs, pleura, peritoneum, liver spleen, intestines, and mesentery There were 50 cows and 30 bovines on this farm, yet none were examined although, obviously, this animal must have been actively infectious for a long period

The Extent to which "Udder" Tuberculosis is being Notified

The records show that the 798 cases reported were for the following conditions —

Tuberculous emaciation or chronic cough = 738
Udder tuberculosis = 60

The udder notifications were fairly uniformly distributed in time, since the notifications in the four four-monthly periods from Sept 1st, 1926, to the end of 1926 were respectively 15, 15, 14, 16 There is therefore no evidence that cases are being reported more frequently as the Order becomes better known The post-mortem findings in these 60 cases were, —

"Advanced" tuberculosis, with udder involvement as part of the general tuberculosis = 33
Considerable lesions in other organs as well as the udder but classed as "not advanced" = 9
Udder lesions only reported = 13
No tuberculosis of the udder = 5

These findings are of considerable interest They show only 13 cases of udder tuberculosis alone, while in 42 the udder involvement was merely part of a general tuberculous infection

While 60 out of 798 cases (7 5 per cent) seems a fair proportion, other facts have to be considered In five cases the swollen or indurated udder which led to the primary notification was found *post mortem* not to be due to tuberculosis Four of these were "advanced" tuberculosis without udder lesions, the fifth animal showed no tuberculosis anywhere Three cases were not primary notifications under the Order, but were detected by the examination of cows in the notified herd Three other cases were discovered in connexion with inspections under the Milk and Dairies Act, 1915—i e , from the examination of herds the milk from which was found to contain tubercle bacilli They were subsequently dealt with under the Tuberculosis Order as a matter of policy and so become included They cannot properly be included as notifications made in connexion with the working of the Order. The exclusion of these 11 cases leaves only 49 cases of udder tuberculosis which were reported under the Order In no less than 33 of these the udder lesions were a more or less accidental concomitant of a state of advanced tuberculosis for which the animals were dealt with We are left with only 10 cases of primary udder tuberculosis reported as primary notifications under the Order It cannot be contended from these figures that the Order is doing anything material to eliminate cows suffering from primary udder tuberculosis

There are some 100,000 cows in the county, and if the proportion of udder tuberculosis is taken as 0 3 per cent (which is well below the figures of most veterinary authorities) this gives about 300 cows as suffering at any one time from tuberculosis of the udder This includes primary udder tuberculosis and cases in which udder disease is part of a general tuberculosis. I have examined the post-mortem records of the whole of the 798 animals slaughtered under the Order to the end of 1926 It is probable that udder disease is not investigated in cases with conspicuous lesions elsewhere, but since March, 1926, veterinary inspectors have been specially asked to investigate and record this point In the later schedules udder disease, positive or negative, is specially mentioned in a material proportion of the cases The following table shows, therefore, the figures recorded separately for the first six months and the last nine months.

Dealing only with the figures for the last nine months of 1926, they show that out of 451 cases there were 85 cases of udder involvement—i e , 18 8 per cent

The animals slaughtered include all bovines, and therefore a proportion are not females If, however, only the figures with definite information supplied as to the condition of the udder are considered, they show that out of 302 cases there was udder involvement in 85 (28 per cent) A total of 85 cases of udder disease falls very far short of the estimated number of 300, and it is evident that the majority of cases of udder tuberculosis are not being dealt with under the Order It must, however, be credited as one satisfactory feature of the Order that during 16 months working 131 cows with definite disease of the udder, the majority of which were supplying milk for human consumption, were destroyed

Post-mortem findings	Sept 1st, 1925, to March 31st, 1926	Last 9 months of 1926	Total
" Advanced "—			
Condition of udder not mentioned	177	113	290
Udder mentioned as not involved	—	109	109
With udder involvement	34	63	97
" Not advanced "—			
Condition of udder not mentioned	122	33	155
Udder mentioned as not involved	—	108	108
With udder involvement	4	17	21
Udder tuberculous lesions mainly or only	8	5	13
Animals not tuberculous	2	3	5
—	347	451	798

The Extent to which Laboratory Facilities are being Utilised to Ascertain if Suspected Animals belong to one of the Designated Types of Tuberculosis

Laboratory facilities are provided free of cost, the work being done in the county laboratory An outfit and all information is sent on request Out of the whole 798 cases laboratory diagnosis is reported as made use of in only 15 instances Four of these do not properly come under the Order as they were four positive cases detected under the Milk and Dairies Act, 1915, and merely slaughtered under the Order. Excluding these the other cases were —

In 4 the veterinary surgeon reported he had examined the milk and found tubercle bacilli

In 1 the veterinary surgeon examined material from a discharging neck gland and found tubercle bacilli

In 6 cases samples of milk were examined in the county laboratory (5 positive)

These figures show that laboratory diagnosis is hardly being used at all This is a significant subsidiary proof that it is only advanced cases, easily recognised clinically, which are being dealt with, and that no endeavour is being made to eliminate udder tuberculosis All experienced veterinary surgeons are aware of the need for bacteriological assistance to diagnose early and doubtful cases of udder tuberculosis I have investigated, accompanied by a veterinary surgeon, a good many herds, the milk from which has yielded tubercle bacilli Invariably such herds have contained cows which showed mammary abnormalities which the veterinary surgeon was unable to exclude as not tuberculous without a bacteriological investigation of the milk It is true most of these have been negative bacteriologically, but the fact illustrates the necessity of bacteriological examinations in doubtful cases I trace part of this neglect of laboratory assistance to the fact that no conference of veterinary surgeons working the Order was ever held, and that no whole-time veterinary officer was appointed to coordinate the work

Disinfection of Premises after " Open " Cases of Tuberculosis have been Destroyed

The requirements of the Order (Section 13) are very vague, and if disinfection at all is to be carried out or how it is to be done is left to the discretion of the police Although we may not all agree as to the practical utility of disinfection in such cases, the disinfection of cowsheds is a valuable method of bringing home to the cow-keeper the infectious nature of these open cases and the importance of reducing infection Personally, I think disinfection is itself a valuable preventive measure if adequately carried out Disinfection is a scientific matter, and disinfection of cowsheds particularly difficult One is left wondering what part of the training of the police fits them for the exercise of these functions and without expert guidance In Somerset I have drawn up a simple procedure for disinfection, and the chief constable has issued instructions for disinfection to be carried out along those lines This, however, is outside the Order, and there is nothing in the Order suggesting obtaining the advice of an expert or indeed suggesting that disinfection should be generally carried out I fancy an inquiry as to the procedure followed in different areas would be illuminating

Summary

Assuming, as I am compelled to do, that the above account of the actual working methods of this Order is in no way peculiar or abnormal, it gives a clear idea of what is being done, and furnishes a basis on which to frame an opinion as to what is likely to be accomplished No effective steps are being taken to explain to the owners of the cows the real nature of tuberculosis, the economic importance of eliminating it, the preventive possibilities and aims of the Order the objective signs in cattle to look out for, or to offer veterinary and laboratory help to detect these dangerous animals in the early stages of their growing infectivity Simple and clearly written instructions as to their responsibilities under the Order are not issued The great bulk of the animals slaughtered under it are destroyed only after they have been highly infective for a long antecedent period, and after they have had prolonged opportunities to infect the other animals in the herd and the byres. They are slaughtered when much of the harm they are going to do has been done No effective steps are taken to carry out the printed recommendations of the Board of Agriculture in regard to the detailed examination of the other animals in the herd, even when the slaughtered animals are in an advanced stage of tuberculosis, and suffer from such infective conditions as severe chronic cough or diarrhœa Such disinfection as is practised is in the hands of the police, and is entirely unsupervised by anyone who knows what disinfection means The elimination of tuberculosis of the udder is, in the main, neglected, and no effective steps are taken to encourage the use of bacteriological methods of diagnosis The cost of working the Order is considerable both for compensation and administration, and being without any preventive outlook it is difficult to see what is the gain to the community from this heavy expenditure

Perhaps a clearer appreciation of the futility of the Order, as it is being worked, will be obtained by imagining our preventive work against human tuberculosis carried out along these lines No steps would be taken to enlighten householders where there was an advanced case of tuberculosis of the dangers of infection to the other inmates or to explain how the disease is spread No action would be taken to isolate or remove the advanced case until he or she had been actively infectious for a very long period, possibly a year or more When nearing his end, the case would be removed from the house (the equivalent of slaughter for cows) No steps would be taken to examine the contacts to see if they had tuberculosis and no advice would be given in regard to them The police would then be allowed to disinfect according to the ideas of the chief constable, but no officer experienced in disinfection would be permitted to interfere Finally, the local authority would pay the householder a sum of money because he had had an advanced case of tuberculosis in his house

It is not the purpose of this paper to discuss the best way to deal with the very difficult problem of bovine tuberculosis On the other hand, assuming that the principle of working along the lines of the Tuber culosis Order is retained, it is perhaps worth while to indicate certain directions along which, in my opinion, its working might be improved

Tuberculosis is a cause of enormous financial loss to the farmer, breeder and butcher. Authorities agree that, quite apart from any question of human infection, it is of the highest benefit to agriculture to eliminate it or at least reduce its ravages Part of the success of methods for the reduction of human tuberculosis undoubtedly are due to the persistent efforts which have been made to enlighten the public as to its methods of spread and the feasibility and importance of prevention The same policy is necessary as regards bovine tuberculosis To throw upon the farmer the duty of detecting and notifying such highly technical conditions as tuberculosis of the udder, tuberculous emaciation and chronic cough, accompanied by definite clinical signs of tuberculosis without giving him advice or guidance can end in nothing but the notification of animals in a highly advanced condition, and after they have spread much infective material My figures show that more than three-quarters of the notifications were directly made by the owners I am aware that agriculturists can obtain excellent leaflets from the Board of Agriculture on many subjects, including tuberculosis, but I am unaware of any systematic educational efforts being carried out along the lines I have indicated

Such educational efforts cannot teach the owners of herds how to diagnose tuberculosis, and this alone is not enough They must be made interested and brought to realise that the presence of these "open" cases is a direct menace to the healthiness of their herds, and that it is financially to their advantage to eliminate them as soon as possible It should be made a duty under the Order to report all animals *suspected* to belong to one of the designated groups To be effective, this must go hand in hand with the education just mentioned as to the financial advantage of eliminating these animals The local authority should provide veterinary assistance, free of charge, to ascertain if these suspected animals did come under the Order As a natural corollary any owner found to have an animal in an advanced stage of tuberculosis which he should have and did not report as a suspected animal would be fined, and no compensation paid for slaughter. This would increase his interest in the problem The benefit of free veterinary assistance for suspected animals would be of great assistance to owners of herds, and only the neglectful indifferent farmer would be penalised It would prevent some of the scandals which occur at present of cows being deliberately milked to the bitter end although clearly in an advanced stage of tuberculosis, and then when no longer of use as milkers, being reported and compensation claimed

A system of regular veterinary inspection of dairy cows is obviously a much better procedure than the above as a means of reducing tuberculosis but the cost is prohibitive, if done adequately As a step towards this goal and one costing very much less money, is the examination of suspected animals When a veterinary surgeon is on a farm examining a notified animal it does not take long to examine the other animals, and it should be done as a routine measure It should not be left to the discretion of the veterinary inspector, since when the local authority paying him his fees discourages such examinations it puts him in a highly invidious position It should be a duty, and a proper entry should be made on his return giving the number of bovines examined and stating definitely that in his opinion none or which come under the designated groups and giving particulars of those which are suspicious In view of the difficulty of the diagnosis of udder tuberculosis in its early stages, there is need to encourage and facilitate a much greater use of bacteriology as an aid I am decidedly of opinion that these examinations should be carried out by a competent bacteriologist in a properly equipped laboratory

The whole question of the administration of this Order needs revision From communications from other county medical officers it is evident that in most counties it is administered by the Agricultural Committee, and without any liaison with the Public Health Committee or its medical officer of health The general procedure seems to be to carry it out by means of part-time veterinary surgeons and without any controlling expert There is no expert to attend the committee and advise as to the proper way to work the Order There is no expert to see that the details of the Order are carried out as they should be In some places the chief constable seems to be the controlling official. The inevitable result is that its preventive possibilities are overlooked, and the Order is looked upon as something to be worked as economically as possible, and administrative endeavour is tuned to the reduction of the cost of its working To be of any lasting value the Order must be worked on preventive lines with a preventive outlook, and this means the guidance of an expert in preventive work To do so means a much greater expenditure in the earlier years, but one which ought to steadily diminish. (I pointed this out in 1913 in connexion with the Tuberculosis Order, 1913) The present procedure means a heavy expenditure which is not likely to show any material diminution year by year, since I cannot see that any prevention of tuberculosis is likely to result To spend more money initially and do real preventive work is much sounder economy than to cut down costs to the lowest possible, and as a result waste all the money as regards doing anything to reduce the spread of infection

Improvements are also necessary on the technical side. For reasons somewhat similar to those which make whole-time medical officers of health more effective and untrammelled than part-time medical officers, whole-time veterinary inspectors to work the Order are to be preferred Financial considerations do not make this practicable in most counties at the present time I regard it as essential, however, that each county of any size should have at least one whole-time veterinary surgeon on its staff He would be the expert official who would advise the Agriculture Committee in regard to the working of the Order, and who would control the work of the part-time men and unify their practices He would also be able to carry out a number of the examinations himself Under the Milk and Dairies (Consolidation) Act, 1915, and the Milk and Dairies Order, 1926, the county councils have considerable duties and powers with regard to the inspection and examination of cows, and these would be carried out by this whole-time officer These powers are worked by the Public Health Committees, and this Officer should be on the staff of the county medical officer of health and under the Public Health Committee This would ensure that coordination of effort which is so lacking at present and would help to give the preventive outlook to the working of the Tuberculosis Order, 1925

Assuming the continuance of the principles of the Tuberculosis Order as the official method of reducing tuberculosis, I submit that unless a radical change of procedure is instituted very little will be accomplished in the way of reducing bovine tuberculosis; indeed it is likely to do harm, since the money available for tuberculosis prevention and reduction is limited To drain it away along a channel which has little or no preventive prospects will prevent it being applied in directions where it might be beneficial

RONTGEN SOCIETY—A general meeting of this Society will be held on Tuesday, April 5th, at 8 15 P.M , in the British Institute of Radiology, 32, Welbeck-street, London, W 1 Dr J V Sparks will read a paper on the Uses of Lipiodol as an Aid to Diagnosis in Diseases of the Chest, and Mr F Melville will speak on X Ray Cinematography

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE FIRST REPORT FOR 1926.

Dr. R J. Moule Horne's report for the Borough of Poole is the first of the 1926 Reports to reach us The following are some of the statistics for his district. Estimated (R G) population, 49,150, birth-rate, 17 5; death-rate per 1000 of the population (all causes), 11 25, tuberculosis, 1 04, cancer, 1 62, respiratory diseases with influenza, 1 5, heart disease, 1 5 Death-rates per 1000 births. neonatal, 30, infantile, 53; maternal from childbirth, 3 5

Poole, Dr Horne tells us, is the largest town in Dorset and is rapidly increasing in popularity as an all-the-year round health resort, especially for people who have spent years in the tropics The enclosed waters of the harbour and the shelter of the Purbeck Hills temper the summer heat and the winter cold and the town escapes the sea-mists of the coast-line The rapid development threatens the pine-clad areas and "if," he warns his fellow-citizens, "Poole will maintain its pride, it must preserve its pines." The average yearly rainfall is 31 in and the sunshine 1715 hours The industries are not unhealthy—e g, pottery, brick, earthenware, and tile-manufacturing, fishing, &c—but there is an undesirably large percentage of unskilled labour associated with the docks and quay The number of the unemployed gradually decreased from 1179 in 1921 to 361 in 1925 but in 1926 there was a set-back to 625.

Poole is well off for parks and open spaces and Alderman H S Carter, the present mayor, has just presented a playing field to the borough The population fluctuates year by year according to the varying influx of mostly elderly residents The housing shortage does not appear to be acute but at the end of 1926 it was estimated at 484 houses When the death-rate was corrected for the unusual age constitution of the population, the rate of 11 25 becomes 9 45 The corporation water-works supply a hard chlorinated water from deep wells in the Corfe Hills, but about 6000 of the population are supplied by the Bournemouth Water Company The rate of building tends to outrun the provision of sewers and roads, and there are 180 more cesspools to be emptied by the health department than was the case five years ago and a further 100 will be added in 1927 In certain weathers access to the houses for this service is impossible owing to the state of the roads One objectionable refuse tip was closed during the year The deposit of the refuse is used for reclaiming land in two areas, and Dr Horne hopes that these areas will be rapidly filled up and a more sanitary method of disposal adopted The public lime-washing of courts and alleys is said to have a stimulating effect on the adjoining householders

The open air swimming-bath at Baiter is well used during the summer months and it is proposed to have a second bath in another situation Figures are given which indicate a decline in the rat population as the result of vigorous measures taken during the last five years During the summer months the fresh-water lakes and ponds are sprayed with paraffin in order to keep down the mosquitoes There are 14 private slaughter-houses scattered about the borough and a considerable proportion of the Bournemouth meat-supply is derived therefrom The new meat regulations have entailed much more work on the sanitary inspectors owing to the butchers having to give three hours' notice of intention to slaughter Thus instead of about 400 visits to slaughter-houses during the year there were 1160 during 1926 Dr Horne would much like to see a modern public slaughter-house erected for the borough Poole oysters were a delicacy relished by the Romans Nowadays with a population of 200 000 living near the bay and harbour the oysters dredged from the harbour have to be relaid for 14 days in the Arne reach prior to their sale in the open market During the last season licence was given for the dredging of 600,000 oysters

The infant mortality report shows that there were 44 stillbirths and 46 deaths of infants, and that the mortality for the one to five age-group is only half of what it was 15 years ago, and has, in fact, during that period improved more than the infant mortality The number of cases of notified ophthalmia neonatorum has fallen gradually from 21 in 1921 to three in 1926. Full sight was preserved in all, with the exception of one impaired vision in 1921 There are 16 elementary schools with 6275 names on the register The head of each school was provided during the year with a well-equipped emergency dressing outfit for first-aid The school dentist inspected 5210 children, of whom 3340 were ascertained to require treatment, and 1677 actually attended the minor ailments clinic and received treatment The scheme of treatment charges has affected the dental cases more than any other branch. During the last three years the receipts from fees have been £8 12*s*, £13 3*s*, and £13 for dental treatment and £33 10*s*, £33 12*s* 6*d* and £34 11*s* 6*d* for treatment of all kinds It is pertinent to ask what was the actual cost of collecting these small totals of fees

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 12TH, 1927.

Notifications—The following cases of infectious disease were notified during the week:—Small-pox, 442 (last week 412), scarlet fever, 1400; diphtheria, 942, enteric fever, 65, pneumonia, 1580 (last week 2379), puerperal fever, 39, puerperal pyrexia, 129, cerebro-spinal fever, 9, acute poliomyelitis, 9, acute polioencephalitis, 4, encephalitis lethargica, 30, dysentery, 10, ophthalmia neonatorum, 135 No case of cholera, plague or typhus fever was notified during the week

Deaths—In the aggregate of great towns including London there were no deaths from small-pox, 4 (0) from enteric fever, 52 (0) from measles, 2 (0) from scarlet fever, 86 (16) from whooping-cough, 30 (10) from diphtheria, 44 (15) from diarrhœa and enteritis under two years, and 342 (33) from influenza

Small-pox in Scotland—At the beginning of the week the number of small-pox cases reported in Dundee amounted to 33, and extra accommodation was being arranged for at the small-pox hospital

The Services.

ROYAL NAVAL MEDICAL SERVICES

Surg-Lt C R Boland to *Widgeon*

ROYAL ARMY MEDICAL CORPS

War Office appointment—Maj C J Coppinger to be Asst Dir of Pathology, vice Lt-Col and Bt-Col A. E Hamerton

Maj J. H Robinson to be Temp Capt, and relinquishes the rank of Maj

Capt J W Malcolm is restd to the estabt.

Capt E M Townsend to be Maj (Prov)

Henry A Ferguson to be temp Lt

Hygiene Companies—Capt J B McGovern to comd the 7th (Southern) Hygiene Co

MILITIA

Majs L W O Taylor and G F Y Leary relinquish their commns, and retain the rank of Maj

Maj T. Walker relinquishes his commn, and retains the rank of Maj

ROYAL AIR FORCE.

Flight-Lt L C Palmer-Jones is granted a permanent commission in this rank.

VACCINATION AND ENCEPHALITIS

To the Editor of THE LANCET.

SIR,—As one who has performed vaccination on well over 22,000 occasions during the last 43 years, I was much interested in reading your article (March 19th, p 619) on Acute Disease of the Central Nervous System associated with Vaccination In my early days vaccination was carried out with no aseptic precaution, arm-to-arm vaccine was used, and no dressing was applied—unless by an "experienced neighbour" who advised the application of bacon fat, goose grease, or some other irritating unguent I saw many bad arms in those days Later I employed commercial lymph, which proved very irregular in action, sometimes intensive, sometimes abortive At this stage a dressing of boric lint was applied, and the violent reactions were much *diminished* During the last 30 years the operation has been carried out under strict aseptic rules with fresh Government lymph, and the result has been excellent

I have therefore witnessed vaccination carried out in all its various methods, and I can emphatically state that I have never seen a sequela resembling encephalitis in any of its forms Encephalitis lethargica is, as the article states, a comparatively new disease; but had such symptoms followed vaccination in the earlier period of the century, I have no hesitation in saying it would have attracted the attention of the dullest practitioner Bastiaanse gives a clue to the suggested association He and others state that "during February, March, and April, 1925, *about 122,000* persons were vaccinated, and 24 cases of postvaccinal encephalitis occurred", but during the other nine months of the year 151,000 persons were vaccinated, and only seven cases occurred, Surely this points to a seasonal cause, and has no relation to vaccination? Again Bastiaanse admits that the cases did not conform to the usual type of encephalitis lethargica since the onset was more sudden (? previous infection) and the after effects varied

I submit that the cases reported were already infected prior to vaccination

I am, Sir, yours faithfully,
BOUVERIE F P MCDONALD, M D
Wallasey, March 27th, 1927.

OPHTHALMIC BENEFIT

To the Editor of THE LANCET

SIR,—Sooner or later we all have to think about wearing glasses, and are most grateful when medical confreres kindly prescribe them for us, but it is a fact that only *ourselves and our* wealthier patients on the one hand, and hospital patients on the other, are in a position to take advantage of this exceptional skill Is there not then, a wide field for those services by trained opticians so definitely supported by Mr Adrian Caddy, and yet as harshly scorned by Dr Alex Lumsden in recent issues of THE LANCET?

This question of efficient sight-testing is very important to all of us who in general practice—visiting or consulting—*are being* asked for directions about it almost daily Mr Caddy *says that* "the opticians in 80 per cent of cases *prescribe* correct glasses and give their patients satisfaction", but Dr Lumsden holds that this figure is "pure assumption and therefore valueless"

What is the truth about this? It is far too serious a matter to be left thus uncertain, and I am wondering how many fellow-practitioners will agree with me that there is considerable dissatisfaction amongst patients at the expensive services of ophthalmic surgeons, and not too certain results obtained in this particular branch of ophthalmic practice Also I should be interested to know if there are other medical men who, like myself, know of many patients who have been perfectly well-suited by opticians at moderate cost As to the danger of serious organic eye disease being maltreated through patients having their "eyes tested" outside specialist circles, surely as a practical matter this is very small, the patient with glaucoma, new growth, or cataract, for example, will *almost certainly consult a doctor* just as soon if he goes to an optician as if he does *not*

I am, Sir, yours faithfully,
E L HOPEWELL-ASH, M D
Grosvenor-street, W, March 27th, 1927

To the Editor of THE LANCET.

SIR,—I have read with great interest the letter of F.R.C S Oculist on this subject in your issue of March 12th The reasonable tone of the letter leads me to think that the writer, and many other members of his profession, would be prepared to hear the ophthalmic opticians' case.

The contention is advanced that the training of the ophthalmic optician is inadequate It is true that it requires six years *or more to* obtain a medical degree, whereas the modern *optometrist's* training occupies only one half of that period He takes a two years' full-time college course and attends one of the refraction hospitals for a minimum of one year. In addition, the optical student has to pass an entrance examination to the college and to matriculate, or pass a similar examination before qualifying He also takes examinations for his college and hospital certificates, besides those for his qualification diplomas. I would, however, make a few observations in this connexion

1 The course of study of the non-medical refractionist is of a highly specialised nature. It is a fact *that he takes general anatomy*, physiology, histology, embryology, pathology, &c, but much more time is devoted to the study of the eye and its connexions, and to physical and physiological optics, than is the case in the medical curriculum

2 His education is naturally of shorter duration than that of the medical student, as *all treatment*, other than refractive (in which he recognises no higher authority), is outside his sphere His function ends with the *recognition* of general or local pathological conditions The number of drugs which he employs in his practice is small, and he is not required to possess the wide knowledge of materia medica of the physician.

3 The conscientious ophthalmic optician is not satisfied when he has *completed* his three years' training and passed all his examinations He realises the vastness of the fields of investigation and research before him He continues to attend a refraction hospital, and lectures arranged by his local and central associations, and to steadily enlarge his library.

4 His experience is also af a specialised *character*. The general medical practitioner, who practises refraction, may see two or three eye cases a week. The optometrist sees 20, 30, or even more He thus becomes increasingly expert in the use of his instruments and can, and does, readily detect any departure from normality. To instance one important detail; he is so familiar with the variations in normal fundi that he immediately recognises any indication of a general or local pathological condition

F.R C S Oculist makes special mention of glaucoma. This disease, insidious in its incipient stages, probably causes more sleepless nights to refractionists than any other Its importance, is, however, duly emphasised both in his training and his examinations. He is, by the instruction he receives and the practice he *obtains, skilled in the* manipulation of the ophthalmoscope, perimeter scotometer, &c, and appreciates the significance of his findings One refractionist has invented a very useful instrument for detecting the relative scotoma of glaucoma Two other optometrists have carried out some valuable investigations and have devised a very useful method of differentiating between a physiological and glaucomatous halo

F R C S Oculist states that there is no parallel between the optical and dental professions The former is now in a very similar position to that occupied by the latter before passing of the Dental Acts, which, incidentally, received some opposition from medical men Before the establishment of the Dental Register, many inadequately trained and unqualified men were in practice To-day, men who have never used a retinoscope, perimeter, scotometer, phorometer, or keratometer, and have never seen a fundus outside a text-book, are permitted to designate themselves " ophthalmic opticians," " optometrists," or " refractionists," and to represent themselves as qualified to conduct a satisfactory ophthalmic examination It is regrettable that many ophthalmic opticians still retain shop premises It is hoped that this practice will shortly cease

Your correspondent further states that " opticians should not be allowed to test the eyes and supply the glasses as well " Would he also affirm that a physician who dispenses should not be permitted to prescribe drugs, or a dental surgeon to extract the teeth and supply the dentures ? The public, and especially members of kindred professions, appreciate the amount and quality of the services rendered, without payment, by members of the medical profession, at hospitals The profession has earned the esteem of all sections of the community by the way in which its members have carried out this work Ophthalmic opticians are, however, doing similar work. The refraction hospitals are staffed by voluntary workers One refractionist of my acquaintance travels weekly from Bournemouth to London, in order to assist in the work of the London Refraction Hospital, all service and expenses being gratuitous

The suggestion that optometrists should go out of practice is unreasonable and impossible I give two of the many reasons for this statement (1) The non-medical refractionist has spent the best years of his life, and several hundreds of pounds on his training He has served the community well It would be unthinkable to deprive him of his livelihood (2) Optometrists have been examining eyes and prescribing ptical corrections for over 300 years They have one much to make the public " eye-conscious " and o improve the instruments and apparatus which they employ Medical men have only practised refraction, to any extent, for a comparatively short period

The public interest demands a speedy and satisfactory solution to the problem under discussion This can be found by legally recognising the optical profession and thus ensuring, in the future, that every practitioner receives adequate training and passes suitable examinations before being permitted to practise —I am, Sir yours faithfully

Chobham road Woking, Surrey, March 23rd, 1927

To the Editor of The Lancet

Sir —The letters of Mr Adrian Caddy and Mr A G Lumsden in The Lancet (Feb 26th and March 5th respectively) represent almost extreme views on the ophthalmo-optical position

It would appear that Mr Caddy's so-called absence of esprit de corps is due to his lack of dogmatism As correction of many of the statements made by Mr Lumsden would be to general advantage, your kindness in publishing this letter will be appreciated

Although deploring Mr Caddy's vagueness, Mr Lumsden does but " suggest " that " perhaps " Mr Caddy will agree that the modern refractionist is so basely commercial that each client entering his establishment is looked upon as a " sale " instead of a " case " and that none pass out of his doors without being financially the poorer

I regret that Mr Lumsden should display so marked a degree of ignorance on the current position or reveal the type of " optician " with whom he is acquainted, but it is a rule of professional etiquette and a scientific principle that before sweeping statements are made the " facts " on which the statements are based shall at least be verified If Mr Lumsden (or any other so desirous) cares to visit—not the shop—but my consulting-room he will find that in no cases are glasses supplied unnecessarily, or cases, observed to be outside the refractionist's legitimate realm, fail to be referred to the proper authority I have yet to be informed of a patient who has privately consulted an oculist without charge, whatever their refractive condition

It is unfortunate that these two realms of ophthalmology—the medical and the physical, as it were—which should be cooperative, tend to be opposed, for no other reason, apparently, than *£ s d.* Yet I fear that Mr Lumsden has touched on a disastrous field when he mentions the " formidable list " of errors which he could compile from his case-book We also have case-books, and if Mr Lumsden were to furnish some representative cases of " errors " I could supply error for error ad infinitum—provided that only cases by properly qualified men on both sides were cited ; but this ocular sword of Damocles would be of little service in harmonising the two and would be very like " the pot calling the kettle black "

Dictionaries are not text-books but adjuncts to them, and it is dangerous to quote from them In Murray's Dictionary the definition of an oculist is " one versed in the knowledge *or* treatment of eyes," from which it would be possible to infer that in order to conform to this an oculist must either know without treating or treat without knowing ! But no mention is made that a knowledge of the instruments of treatment is necessary, and again a " formidable list " could be produced, such as ordering decentred plano-cyls along their axes with a worked prism in the same direction, &c

Mr Lumsden's ideal method is for the wealthy to go privately to the uncommercial oculist and the unwealthy to go to the same oculist at the hospital This is far from ideal (apart from being impossible), and I sympathise with the harassed oculist who arrives at the hospital clinic to find himself faced with the problem of carrying out anything from 6 to 18 refractions within about two hours Incidentally the end of the two hours usually finds each patient supplied with a prescription and a weary band wending their cycloplegic way to the " optician," who has oft to respond to the appeals of busy clients surprised at the prospect of many hours to come under cycloplegia, by the instillation of eserine or the hasty assembling of the nearest available near vision correction for temporary use

Finally, to balance Mr Lumsden's case of the tailor wearing lenses suitable for compound myopic astigmatism and who required O D + 0 50 ⊂ + 3 50 cyl axis 70° (or was it + 4 00 ⊂ − 3 50 cyl axis 160° ?) I recently examined a young lady of 22 years of age who had been suffering from frontal-parietal-occipital cervical headaches, and had been treated by a medical practitioner with mustard poultices, but to no avail She was almost emmetropic and orthophoric, the only apparent ocular defect being a 15 ° concentric contraction of both fields I referred her to an M.B F R C S , registered on the M O H list of ophthalmic surgeons who, after perusing my full report and examining the patient himself, supplied an almost identical prescription and replied that as he could find no evidence of glaucoma he was unable to account for the constriction of the fields

Will not the solution of these problems be rather by cooperation than by contradiction ?

I am, Sir, yours faithfully,

Sidney H Southgate, F B O A (Exam.)

Horsington House, Woking, March 14th, 1927

To the Editor of The Lancet

Sir,—The recent correspondence in The Lancet concerning ophthalmic benefit for insured persons proves of added interest in consideration of the projected new Bill suggested for the registration of sight-testing opticians. Your issue of Feb. 12th gives a résume of the proposed *Parliamentary Bill.*

Having investigated the status and methods of the registered opticians (optometrists) in the Colonies, I have come to the conclusion that over there, as in Britain, there are many defects in the training and abilities of even the best sight-testing opticians My conclusion is that they are not yet in a fit position to be recognised by this Government and the nation to prescribe lenses for uncomplicated errors of refraction Different conditions in the Colonies necessitate a changed attitude in dealing with errors of refraction amongst the public. The opticians would like to go so far as to make it compulsory for everyone to possess at least two pairs of glasses, one to stimulate the eyes and the other to rest the eyes What would be the result of registration of opticians ? In the first place a tremendous advertising campaign would ensue, such as this country has never seen before, to blaze the information that spectacles alone are able to prevent and cure all diseases of the eye

It is well known that the various organisations and associations of sight-testing opticians are at bitter enmity amongst themselves concerning the opinions they hold of their relative importance To the most casual investigator it is patent that a big cause of this enmity has resulted from quarrels over matters of finance.

One of the leading organisations amongst sight-testing opticians is known as the Joint Council of Qualified Opticians This autocratic body has despotic control over many opticians in England and Wales Named in short the J C Q O (it is a limited company) its chief means of control and domination over its members is that it acts as a financial intermediary between the approved societies or insurance companies and the sight-testing opticians An entrance fee is necessary to join the J C Q.O , an annual subscription is required, and 2½ per cent of all the money paid by the insurance companies for spectacles is deducted as expenses A further percentage is deducted in order to finance the huge advertising campaign which tells us that sight is might and that those opticians who portray the golden eagle in their windows are specially endowed with powers to give glasses to suit all sights or to treat failing sight

It is worthy of note here to remark that the insurance companies allow a testing fee of 5*s* to the optician for every case for which spectacles are supplied The immediate and ultimate desire of the optician is to sell glasses whether necessary or not at the highest possible figure There is no suggestion that this projected registration would put an end to indiscriminate advertising or break up the big profiteering trusts who run multiple shops The optician of to-day now adopts more than ever the attitude of the "dog in the manger" Until a few months ago all insured persons were seen without fee at the hospitals, but, nevertheless, the optician always obtained his profit on the spectacles sold Since the introduction of ophthalmic benefit the optician is very annoyed because he does not invariably receive the testing fee of 5*s* in addition to the profit derived from the spectacles sold Whenever possible the patient is side-tracked from going to visit an ophthalmic surgeon, and for the many doubtful cases the slogan is "Supply some lenses and hope for the best"

The optician is ploughing a lone furrow when he broadcasts to the public that the simple wearing of spectacles will cure all diseases of the eye Reference to the file cards and notes of any ophthalmic surgeon concerning any number of cases taken at random will demonstrate that for the diagnosis and correct interpretation of most diseases of the eye, a knowledge of the function and pathology of the whole body is necessary The relationship between disorders of the eye and the accompanying disorders in the nervous system needs no emphasis· as an example the differential diagnosis of the types of arterio-sclerosis of the retinal vessels, the investigation of partial amblyopias, cases of retrobulbar neuritis. and the ocular defects in such diseases as disseminated sclerosis or tabes dorsalis, belong to the domain of the ophthalmic surgeon alone For the optician to pose before the public as being able to diagnose abnormal conditions of the eye from the medical point of view is an insult to the intelligence of the general public. The optician of to-day is lacking both in scientific ability and experience, and should not be trusted as competent to preserve the vision of the nation.

To emphasise the mistakes constantly made by opticians I will quote three recent cases —

1 A middle-aged lady complaining of misty vision had her glasses changed by an optician three times within six months A diagnosis of subacute iritis with a deposit in anterior chamber as made by an ophthalmic surgeon on first visit After extraction of teeth the condition improved considerably

2 A child, aged 3, treated by an optician for long sight, was found on visit to oculist to have a retro-ocular tumour, and excision of the eye was necessary.

3 A male, aged 50, complained of increasing dimness of vision, and was seen several times by an optician without diagnosis being made On finally going to hospital a diagnosis of early optic atrophy was made, and the patient advised accordingly.

The average optician of to-day devotes too much attention to the commercial side. In contrast with the sight-testing opticians is the National Association of Dispensing Opticians, which represents the dispensing opticians of the country. who carry out most excellent work in arranging for the fitting and decentring of the lenses given in the prescription of the ophthalmic surgeon.

Those opticians pressing for State recognition do not mention incidentally that any individual with a knowledge of salesmanship can learn enough about eye glasses in a space of ten hours to call himself a fully qualified optician What the public does not know, however, is that a period of at least ten years' specialised medical training and surgical experience is necessary before commencing the career of an ophthalmic surgeon

I am, Sir, yours faithfully.

March 26th, 1927 OPHTHALMIC SURGEON

*** The intention of the Minister of Health to set up a Committee to inquire into the question of registering opticians makes it necessary that our readers should be informed on all sides of the subject —ED. L.

VENEREAL DISEASE IN THE MERCANTILE MARINE

To the Editor of THE LANCET.

SIR,—The letter of Dr. L L Burton of New Zealand in your issue of March 26th seems to show that the Government and Port Authorities of New Zealand have not carried out the recommendations contained in the Report (Series P. Seamen No 2) entitled Protection of the Health of Seamen against Venereal Disease, published by the International Labour Office of the League of Nations, Geneva, in July, 1926

The Report was drawn up by a Joint Commission consisting of five representatives of shipowners five representatives of seamen, and two members of the governing body of the International Labour Office. and recommended that the circular published by the British Shipping Federation should be forwarded to various shipowners' and seamens' organisations This circular recommended (1) "the dissemination amongst seamen of exact knowledge of the prevention and cure of venereal diseases," and (2) "the distribution at cost price to seamen of the requisite materials for prevention by immediate self-disinfection" The circular stated that the British Shipping Federation would be prepared to supply suitable literature for gratuitous distribution amongst seamen including a lecture specially written for seamen by myself. The Report also recorded the opinions of various countries in regard to the prevention of venereal disease amongst seamen, such as:

Australia —"Most satisfactory means for the dissemination of exact knowledge amongst seafarers and for immediate self-disinfection have been adopted"

Belgium —"The Statutory Health Commission have approved a scheme giving wide facilities for the supply of disinfectants"

France —"A committee on the prevention of venereal disease has been set up in *connection with the Ministry of* Health and Social Welfare"

Germany —"Shipowners are required to distribute preventive medicines to seamen"

Poland —"The Ministry of Public Health was planning to publish prescriptions in order to enable the population of the ports to avoid infection from venereal disease"

Sweden —"A Royal Ordinance was in preparation prescribing that all ships must keep in stock certain kinds of medicine and other medical articles for the prophylactic and curative treatment of venereal disease"

The protection of the health of seamen against venereal disease is an important part of the general antivenereal campaign The education of seamen in the prevention of venereal disease by immediate self-disinfection is, however, still opposed by a fanatical section of the community who have always obstructed such education of the public However authoritative the body issuing the pronouncements on the subject and however wise and logical their recommendations may be the history of the past ten years makes it clear that the problem will not be seriously grappled until the conspiracy of silence has been finally exposed, and killed by the ridicule it deserves

I am, Sir, yours faithfully,

H WANSEY BAYLY,

Harley-street, W, March 25th, 1927

THE INCIDENCE OF LEAD POISONING

To the Editor of THE LANCET

SIR,—One of your readers at least, who lives abroad, is particularly grateful to you for the full reports of Parliamentary intelligence which you print from week to week The great value of publicity in matters of social medicine is well illustrated by the debate on lead poisoning which you print in the March 5th issue, just received I followed the controversy that was carried on under the able chairmanship of Lord Burnham from day to day, and can testify to the truth of his contention that immense pressure was brought to bear on the conference by the two industries whose interests were involved The only safeguard against the pressure of vested interests is a full ventilation of facts—and bearing in mind that the interests in Great Britain are predominantly those of the white lead industry the British medical profession should be especially informed of all the facts presented by both sides in a conference where both interests are strongly represented It is for this reason that I still regret the exclusion of your correspondent from the sittings of that particular subcommittee in Geneva when the strictly medical evidence was under scientific consideration The matter is not unimportant If it be agreed that the mortality and morbidity due to lead poisoning are preventable, we must not rest until the appropriate legal measures of prevention have been found May you continue by your good offices to hasten that day

I am, Sir, yours faithfully,

P B P

Ohio, March 19th, 1927

ROYAL WATERLOO HOSPITAL —It was stated at the annual court of the Royal Waterloo Hospital for Children and Women, Waterloo-road, London, that the extension now being built would, when opened at the end of May, provide six beds for paying patients, while a further 12 cots would be made available by the transfer of the operating theatre from the old building to the new There are at present 110 cots and beds Arrangements are being made for the equipment of an orthopædic department

SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

MEDICAL, DENTAL, AND PHARMACY BILL.

THAT hardy annual the Medical, Dental, and Pharmacy Bill was once more submitted for second reading in the Union House of Assembly in February

Dr. Malan (Minister for Health), speaking in Afrikaans, said that the Bill was of so urgent a nature that its passage should be no longer delayed It had become urgent first of all from an administrative point of view Medical services in general throughout the Union should be uniform, but to-day the position was that every Province had its own Medical and Pharmacy Acts, with the result that there were at present 16 Medical Acts requiring to be administered by his department Since the Bill was first introduced two medical faculties had been established in South Africa It was essential that the medical profession and the medical faculties should stand in properly defined relation towards each other Another essential point was that the trade in poisons should be brought under proper legal control It had been said that there was no country in the world where it was so easy for a person to become possessed of poisons as South Africa Dr Malan went on to point out the necessity for due protection being extended to dental practitioners who had been thoroughly qualified for their profession The dental mechanic was now really in a better position than the properly qualified man, who fell under the discipline of the Medical Council and was not allowed to advertise The Bill aimed at rectifying this unsatisfactory position The powers of the Medical Councils, as compared with the past, were to be curtailed The Councils would recognise degrees issued in South Africa, and also overseas In regard to the suspension and removal from the roll of persons found guilty of unprofessional conduct, an aggrieved person was given the right of appeal to the Supreme Court instead of to the Minister, as in the past The Minister went on to urge the necessity of a register of persons duly qualified under the Act being kept for the protection of the public Wherever the lives and the interests of the public were concerned, the persons entrusted with the care of such lives must be thoroughly qualified and duly registered. Regarding maternity nurses, the Bill made a great step forward In the past the heavy infantile mortality had been due largely to unqualified maternity nurses The number of qualified maternity nurses, especially in the rural areas, was insufficient, and such areas naturally had to be provided for The Bill laid it down that in certain specified areas nobody would be allowed to practise as a maternity nurse for remuneration unless properly certificated and registered Ninety five per cent of the Bill, said Dr Malan, was non contentious. The most contentious part of the Bill was Clause 34, under which no one not duly qualified would be allowed to practise "for gain," and the word "gain" was defined in the Bill The object was not to prevent a person from being doctored by an unqualified person, but to provide *that no* such unqualified person should be allowed to doctor another person for the purpose of gain Mr. P. Duncan (Yeoville) maintained that the Bill was urgently required in the interests of the public Mr Alexander (Hanover-street, Cape Town) said it was not what was *in the Bill that worried him, but what* was left out of the Bill He felt that drugless healers should receive some recognition in the Bill, provided they could prove that they had received a proper course of training in their particular professions Some of the most eminent men in the country, including the Prime Minister himself, had consulted drugless healers and benefited from their teachings He hoped the Minister would consent to exempt Christian Scientists from the restrictions imposed by the Bill He also pleaded that dental mechanics should be allowed to practise the purely mechanical side of the dental profession in a more unfettered fashion than at present Mr Mosterit (Namaqualand) opposed the Bill because it did not lay down a tariff of charges, and Mr Heyns (Middleburg, Transvaal) opposed it as a measure which would benefit nobody but the doctors The question of fixing doctors' fees was also raised The Minister of the Interior stated that the matter had engaged his attention for a considerable time, and he had at one time had a formula for inclusion in the Bill So great, however, had been the obstacles that he had left the matter alone Instead of ameliorating the position of the poor man, the fixing by law of doctors' fees would cause it to be aggravated, and many a doctor who charged a poor man a low fee would have to raise his charges Also one had to take into account the question of the specialist who was inundated with patients

The Bill was read a second time, and on Feb 14th the House of Assembly went into Committee on the Bill

The Medical Council—On Clause 2, dealing with the constitution of the Medical Council and Pharmacy Board, an amendment was moved to the effect that the Medical Council should be so constituted that the general public and the medical profession be equally represented, lest the medical profession should become too powerful a monopoly

The Minister of the Interior said there might be something in favour of this amendment, even if it only had the effect of removing suspicions which seemed to exist against the Medical Council He was prepared to accept the amendment in part so that the Minister would appoint to the Medical Council four medical practitioners and two persons not registered under the Act There would further be one dentist on the Council This amendment was agreed to The Bill was further considered in Committee on Feb 16th On Clause 24 Mr Heyns (Middleburg) moved the insertion of a proviso to the effect that a person who for five years before the commencement of the operation of the Act had practised as a doctor, and had taken fees for such practice, should be allowed to continue practising The Minister of Public Health declared the amendment to be in direct conflict with the principle of the Bill, and it was negatived Mr Steytler (Albert) moved the insertion of a proviso to the effect that any person not registered in accordance with the Act should be entitled to treat a person who had been abandoned by a medical practitioner and to charge for such treatment The amendment was negatived by 51 votes to 22

On Clause 34, dealing with penalties for practising as a medical practitioner when unregistered, Mr Alexander pleaded for the chiropractor, and moved the insertion of a proviso that nothing in the clause should apply to any drugless healer, who would have to prove to a Board that he was qualified to practise his particular form of healing On the following day the clause was further considered in Committee of the Assembly, and an animated discussion took place

The Minister of Public Health opposed the amendment, observing that the laws all over the world were being tightened up against drugless healers The Minister of Labour (Mr T Boydell) said that a refusal to pass the amendment would put the clock back 50 years by closing the door to new and modern methods of healing He heartily supported the amendment, which simply made provision for the recognition of qualified drugless healers He himself had received greater benefits from drugless healers than from medical men, and he refused to be compelled to go to the latter He was entirely opposed to the monopoly set up by the Bill Mr Duncan challenged the Minister of Labour to tell him any method of healing which had not been carefully inquired into by the medical profession Had the osteopaths and other people referred to ever tried to prove their methods scientifically, or ever submitted them to scientific tests ? He was not a believer in drugs, and he agreed that some medical men believed too much in applying drugs The amendment was eventually negatived by 53 votes to 24, and the clause was passed

Precaution against an Influenza Epidemic

Precautionary measures against an influenza epidemic are being taken by the Pretoria health authorities, who are advertising for persons willing to undertake nursing in the event of an outbreak. Dr Boyd, the M O H , does not anticipate a serious outbreak of influenza, but as influenza is prevalent in England at the present time, he has considered it wise to take precautionary measures, and to have a programme mapped out in event of such an outbreak An elaborate scheme for coping with an epidemic has been worked out in Cape Province

Outbreak of Cerebro-spinal Fever

An outbreak of cerebro-spinal fever in the Vredenburg district of the Cape Province, in the nature of an epidemic, is causing some uneasiness Some 30 cases have occurred during the last two months, a large proportion of them ending fatally

A Hospital Benefaction from Native Chiefs

A noteworthy illustration of the desire of the more advanced native chiefs to coöperate with Europeans in furthering their common interests is afforded by the action of two native chiefs in the Rustenburg area of the Transvaal They have contributed a sum of £700 towards the establishment of native wards at the new Paul Kruger Memorial Hospital which is being erected at Rustenburg Rustenburg has a population of 1733 whites and 960 natives, it is situated 70 miles from Pretoria, and 80 miles from Johannesburg

Government Hospital Inquiry

The Minister of Public Health has appointed a committee to inquire into and report upon certain matters connected with the hospitals and district nursing arrangements in the Union Sir Edward Newbury Thornton will preside, and the terms of reference are to inquire into and report upon the existing public hospital and district nursing accommodation and facilities in the Union, their adequacy and suitability or otherwise, their linking up and coordination by the utilisation of modern facilities for transporting the sick, and by other means with each other, and with institutions for dealing with cases of infectious or communicable diseases, and their future organisation, control, and development under the Provincial administration If deemed advisable by the committee, and with due regard to the existing hospital position and arrangements, the committee will submit recommendations as to the division of each Province into hospital areas, and as to the organisation and administration, including financial arrangements, of the hospital areas so defined , each area is to have at least one adequately equipped central hospital to link up with such subsidiary institutions, cottage hospitals, public dispensaries or clinics stations for district nurses, and so forth, as the committee may consider necessary for providing efficient and economical hospital and sick nursing service for both urban and rural areas

Pretoria's New Hospital

The general hospital shortly to be built in Pretoria will be one of the largest and finest institutions of its kind in the Union, being second only in size to the Johannesburg General Hospital Building plans have been completed the laying out of the grounds decided, and tenders called for the erection of the first block of buildings It is estimated that occupation will have to be deferred until early in 1929 A sum of close on £300,000 has been voted for the hospital There will be a total accommodation for 224 patients Special care is being taken in regard to the construction of a modern children's ward

MEDICINE AND THE LAW

THE HUME-SPRY CASE FURTHER CONSIDERED

"Good faith" and "reasonable care" These are plain words with plain meanings, surely, one might think, wide enough to give ample protection to the medical practitioner who with due regard to the formal requirements of the Lunacy Act signs a medical certificate That in the last resort these words may and do protect is evident from the highly satisfactory verdict given in the Hume-Spry *v* Smith & Another case abruptly concluded last week But that they do not protect the defendant medical practitioners, except where the action does not disclose a prima facie case of bad faith or lack of reasonable care, from a year or more of anxiety, waste of time, and loss of money is equally manifest Certain amendments of the law, discussed in THE LANCET last week, have been proposed, and in the meantime the medical issues of the case deserve careful attention The charge of bad faith appears to have been based on the fact that the defendants made no endeavour by independent inquiries to test the plaintiff's delusions There is no proof that it is the practice, which is not required by the Act, to make such independent inquiries, and, indeed, cases can easily be imagined—the present one, for example—in which such a search carried out by the medical practitioner might have unforeseen consequences and leave the inquirer himself in a very unenviable position An ethical point turns on a matter of great medical interest It will have been observed that an essential part of the medical evidence for the plaintiff was that reasonable care had not been exercised by the defendants because they had not made a physical examination of Mr Hume-Spry In varying degree this remarkable doctrine was supported by the plaintiff's expert witnesses, though one of them merely said that it was necessary to make a physical examination to exclude the possibility of the mental symptoms arising from some bodily illness All of this is quite immaterial in the certification of the insane, in which the medical practitioner is concerned solely with the mind and conduct of the person examined It seems at any rate possible that if greater weight had been given to these considerations more than a year ago when the order of the Master in Chambers staying this action was reversed by the Court of Appeal, the case would not have been allowed to go forward for trial by jury and much time, worry, and expense would have been saved On the other hand, it is probable that only trial by jury could have vindicated so completely the defendants and have so utterly dissipated the aspersions cast on several persons who had the misfortune to be involved

---

MEDICAL SOCIETY OF MANCHESTER —Prof J S Haldane will on April 6th give an address to this Society entitled Biology and Medicine

LONDON FEMALE LOCK HOSPITAL —On March 23rd Lord Radstock opened a new operating theatre and genito-urinary department at this hospital, which is now in its 180th year Mr Charles Gibbs, senior surgeon, said that the hospital now became a complete unit It would be possible henceforward to deal with patients suffering from abdominal complications causing either chronic disease or immediate danger to life These had previously been transferred to Charing Cross Hospital, which had been regrettable scientifically because they were preferably treated at the hospital to which they came for treatment of their primary infection The new genito-urinary department would be able to deal with diseases coincident with venereal infection The ward would also be available for the more serious operative procedures of childbirth It was proposed to admit women who could not pay anything at all and also those who could afford to pay a small sum per week Until now there had been no place in London where poor women suffering from genito-urinary and allied diseases could be taken into hospital and treated for a small weekly payment Mr Gibbs made a special appeal for the gift of X ray equipment.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

THE CARE OF PHYSICALLY AND MENTALLY DEFECTIVE CHILDREN

ON Thursday, March 24th, the motion for the second reading of the Consolidated Fund (No 1) Bill,

Mr TREVELYAN said that the Board of Education ought not to be issuing economy circular after economy circular but ought to be dealing with black-listed schools There were 623 schools that had been absolutely condemned and which had not been replaced, they contained 160,000 children In making their list of really insanitary and unsatisfactory schools which could not be tolerated any longer the Board adopted a very moderate and merciful standard Yet there were 600 schools which had been absolutely condemned by any conceivable standard which they possessed They had been told that some provision had been made in the case of provided schools, but it was made quite clear that in the case of what must be the majority of these schools, mainly the non-provided schools practically nothing had been done The Board of Education could not play two rôles It could act as a department of the Treasury, and if economy was its primary motive education could not progress very much

Mr HARRIS said that in Circular 1358, dated March 31st, 1925, the President of the Board of Education said "My obligation is to ensure that every provision should be made for the ascertainment and treatment of children suffering from incurable infirmities, or infirmities the effect of which can in some measure be mitigated by special teaching, so that they may not become a permanent burden on the community to which they belong" Those were excellent sentiments in principle After the lapse of two years the right hon gentleman changed his attitude In his later Circular No 1388, dated February of this year, he had discovered that the whole subject needed inquiring into He said "In regard to the provision for mentally defective children, authorities will be aware that this very difficult problem is now being explored by a special committee and save in exceptional circumstances it would not seem desirable to incur any expenditure on new schools, and such children ought to be provided for in existing schools" What a pity the right hon gentleman did not think of that two years ago and appoint a committee of inquiry then

Lord E PERCY A committee was appointed by my predecessor

Mr HARRIS said the right hon gentleman ought to have been conscious of that when he sent out his circular in 1925 He suddenly remembered this committee in 1927 when he wished to make an excuse for discouraging local authorities from doing their duty in providing for these pathetic cases

Mr MORRISON said he wished to draw the attention of the President of the Board of Education to the question of the subnormal children in this country and the effects of his policy in regard to them during the past two years. Under the existing law local education authorities were required to make educational provision for all children who were defective and who were capable of benefiting therefrom. The figures given in the House nearly four years ago on this subject were very alarming, because they showed that many authorities were not carrying out the law A good deal of pressure was brought to bear on the Board of Education and Mr TREVELYAN, who was then President of the Board, issued Circular 1341 dealing with special schools for mentally defective children in which he pointed out that "the problem is too urgent to be left till it is solved in its entirety in the manner which the Statutes contemplate, and which alone can provide a satisfactory solution" According to the official figures there were 2000 blind children in this country and of those there were 262 who were not attending any school at all, and 63 who were attending public elementary school That was an extraordinary state of affairs, and seemed to be not only a waste of money, but also a very serious handicap on the teachers The total of the children who were partially blind was 4692 and out of that number 2069 were in public elementary schools and 339 were not attending any school at all If it was possible to do such wonderful work as had been done for the soldiers blinded in the war at St Dunstan's, the same specialised training applied to the partially blind children would produce even more wonderful results, because the institutions would get hold of the children at a much younger age Experience indicated that 50 per cent of those trained in special schools for blind children could be equipped to earn a useful livelihood Surely the President of the Board ought to try to extend that work instead of hindering it With regard to deaf children, it had been ascertained that there were 4154 totally deaf children in this country and of those 319 attended ordinary schools They were stone deaf, and 247 were not attending any school at all At the annual meeting last week of the National College of Teachers a resolution was passed viewing with apprehension the possible consequences to deaf children involved in the circular issued by the Board of Education They said that these deaf and partially deaf children if they did not receive a specialised education, were frequently taken to be insane later in life, when they were not really insane at all There were 2170 partially deaf children in this country and 1632 of those were in ordinary schools and 80 were not in any school at all These figures were underestimated With regard to physically defective children including cripples, those suffering from tuberculosis and delicate children who required open-air schools, the official figures showed a total of 142,889, and of these 94,332 were in public elementary schools and 18,931 were not in any school That showed that there were 113,263 physically defective children not receiving the specialised education which their disability required, and whose chances of earning a living were seriously endangered thereby Economical proposals applied to physically defective children in the way suggested was a penny wise and pound foolish policy Mentally defective children were referred to in Circular 1388, which showed that out of 33,000 mentally defective children in England and Wales 12,470 were attending elementary schools who should not be there at all Included in the 33,000 there were 3872 who were educable, but who were not attending any school at all There were still 110 authorities who had made no provision for teaching these children, although they could be compelled by law to make such provision The circular issued by the Board of Education was really the meanest form of economy that the mind of man ever conceived The records of the existing schools for mentally defective children showed that from 60 to 70 per cent of these children were at work two years after leaving those schools He wished to know whether the suggestion behind this circular was that there should be nothing further done by local authorities to provide for mentally defective children, or was the suggestion that the Board of Education officials were working out some new idea under which the mentally subnormal children should remain in schools for defectives until they were 11 years of age? Any such suggestion would mean an entire reconsideration of the question of staffing The presence of these children in the ordinary classes hampered the progress of the normal children Out of the 33,000 educable mentally defective children in England and Wales on March 31st last only 17,154 could be accommodated The effect of the official circular would be to hold up indefinitely all provision for dealing with one of the most urgent and serious educational and social problems which they had to deal with at the present time The doctors of the School Medical Service could never do the work of the teacher, so far as mentally defective children were concerned

Lord E Percy (President of the Board of Education) replying to the debate, said that the fact that the blind children were not attending special schools was due, in the main, either to the unwillingness of the parents to have their children placed in these schools, or to the children having arrived at an age at which the obligations to attend the schools no longer held good The real main problem of the mentally and physically defectives at the present moment was that there were areas where there were only a few defective children and not enough for a special school They could only be dealt with either by having a class in connexion with an elementary school, or by sending them to a residential institution After all, the parents had something to say about their defective children, and it was not always easy to deal with them for that reason That these special schools were able to do some work he did not deny, but that the children became self-supporting, or that the schools were necessarily on the best lines for the good of the children was a very grave question The powers of compulsion which the Board possessed in regard to mentally defective children constituted the gravest responsibility which the Board had got, and if they dealt with those children wrongly it might be better that they had never dealt with them at all Great play had been made in the debate about the mysterious committee on mental deficiency, as if it had been suddenly revealed But if hon Members had ever read the reports on the health of school-children by the Chief Medical Officer of the Board of Education for 1924 they would have found on page 145 a long footnote explaining the composition of that committee and a considerable passage in which its object was explained Teachers were not excluded from it, and one member of the committee was Miss Redfern, the headmistress of a residential school for mentally defective children. As regards the question of the black-listed schools the noble lord said that the bulk of the provided schools would be dealt with by the end of the programme period, and without laying down a hard-and-fast date for the termination of recognition, he thought that every local authority should proceed on the assumption that all the A schools on the list, and the bulk of the B schools, should have been dealt with by the beginning of the school year—that meant September, 1930 The position in regard to the non-provided schools was not quite so clear, but he did not think that the progress up to date had been unsatisfactory The managers of non-provided schools had to face many difficulties

Mr Morgan Jones said that in reading the report presented by Sir George Newman recently, he noticed that he said that in 1900 there were 142,912 children under the age of 11 who died In 1921 that number had been substantially reduced but it was still colossal, it was reduced to 112 906 In 1925 it was still 96,669 Out of that figure 81,080 were children under 5 That was a staggering and alarming figure, and it entitled them to urge that some additional provision should be made to bring these younger children, at any rate at the age of 4 or 5, into some form of nursery school where their physique as well as their moral training might be more amply looked after According to the report of the medical officer of the London County Council, Dr Menzies, there were 10,000 children who had suffered, or were suffering from rheumatic symptoms Very substantial work had been done in this department, but, having regard to the effects in later life of this disease, there was a strong case for the intensification of the medical service attached to the educational service throughout the country

The Duchess of Atholl (Parliamentary Secretary to the Board of Education) said that everyone who had read the report of the medical officer on the health of young children must feel grave concern at the figures given with regard to children under 5 years of age The nursery schools were doing splendid work in improving the health and general training of young children But they did not look for health in this matter from nursery schools alone They also recognised the valuable work done by day nurseries and the extent to which voluntary effort had contributed to this task With the present financial difficulties with which the country was faced anyone responsible for educational administration would welcome every help that voluntary effort could give Rheumatism was another disquieting feature disclosed in the principal medical officer's report She could assure the House that children suffering from heart trouble caused by rheumatic affection were to an increasing extent being admitted to the physically defective schools and a very welcome feature of the problem of the physically defective child was that in some areas—thanks to the provision of orthopædic treatment for the crippled child, which if given at a sufficiently early age, offered hope of a real cure—they were finding that increasing space was being found for the rheumatic children, or children with affected hearts, in schools originally intended for the crippled child She thought they were doing something in an ever-increasing degree to meet the unhappy case of these children

The Bill was read a second time

HOUSE OF LORDS

Wednesday, March 23rd

Air Force Accidents

Lord Gorell called attention to the frequency of accidents in the Royal Air Force He said that the Secretary of State for Air had said that there were 58 fatal accidents in the Force last year That was an average of more than one a week, and only in the previous week there were some more. The recent statement by the Prime Minister had not entirely removed all the sense of uneasiness on this question Most of these accidents occurred, as far as could be known from certain definite causes He thought that it was admitted that the "stalling" of a machine, especially when it was near the ground, was at any rate a very frequent cause of these accidents He found among the technical experts criticism of the Air Ministry for having been rather dilatory in testing and possibly applying safety devices He did not associate himself with those criticisms, but he would like further information on the matter

The Duke of Sutherland (Paymaster-General), replying for the Air Ministry, said that from some criticism which had recently appeared in the Press, and had even been heard in the House of Commons, it might almost be supposed that the Air Ministry kept no proper record or statistics, but simply accepted the accidents as necessary concomitants of aviation It might even be supposed that the Air Ministry made no real endeavour to reduce the number of these accidents Nothing was further from the truth The Prime Minister had satisfied himself that the fullest statistics had been kept since the war and that the whole

MEDICINE AND THE LAW

THE HUME-SPRY CASE FURTHER CONSIDERED

"Good faith" and "reasonable care" These are plain words with plain meanings, surely, one might think, wide enough to give ample protection to the medical practitioner who with due regard to the formal requirements of the Lunacy Act signs a medical certificate That in the last resort these words may and do protect is evident from the highly satisfactory verdict given in the Hume-Spry *v* Smith & Another case abruptly concluded last week But that they do not protect the defendant medical practitioners except where the action does not disclose a prima facie case of bad faith or lack of reasonable care, from a year or more of anxiety, waste of time, and loss of money is equally manifest Certain amendments of the law, discussed in THE LANCET last week, have been proposed, and in the meantime the medical issues of the case deserve careful attention The charge of bad faith appears to have been based on the fact that the defendants made no endeavour by independent inquiries to test the plaintiff's delusions There is no proof that it is the practice, which is not required by the Act, to make such independent inquiries, and, indeed, cases can easily be imagined—the present one, for example—in which such a search carried out by the medical practitioner might have unforeseen consequences and leave the inquirer himself in a very unenviable position An ethical point turns on a matter of great medical interest It will have been observed that an essential part of the medical evidence for the plaintiff was that reasonable care had not been exercised by the defendants because they had not made a physical examination of Mr Hume-Spry In varying degree this remarkable doctrine was supported by the plaintiff's expert witnesses, though one of them merely said that it was necessary to make a physical examination to exclude the possibility of the mental symptoms arising from some bodily illness All of this is quite immaterial in the certification of the insane, in which the medical practitioner is concerned solely with the mind and conduct of the person examined It seems at any rate possible that if greater weight had been given to these considerations more than a year ago when the order of the Master in Chambers staying this action was reversed by the Court of Appeal, the case would not have been allowed to go forward for trial by jury and much time, worry and expense would have been saved On the other hand, it is probable that only trial by jury could have vindicated so completely the defendants and have so utterly dissipated the aspersions cast on several persons who had the misfortune to be involved

---

MEDICAL SOCIETY OF MANCHESTER—Prof J S Haldane will on April 6th give an address to this Society entitled Biology and Medicine

LONDON FEMALE LOCK HOSPITAL—On March 23rd Lord Radstock opened a new operating theatre and genito-urinary department at this hospital, which is now in its 180th year Mr Charles Gibbs, senior surgeon, said that the hospital now became a complete unit It would be possible henceforward to deal with patients suffering from abdominal complications causing either chronic disease or immediate danger to life These had previously been transferred to Charing Cross Hospital, which had been regrettable scientifically because they were preferably treated at the hospital to which they came for treatment of their primary infection The new genito urinary department would be able to deal with diseases coincident with venereal infection The ward would also be available for the more serious operative procedures of childbirth It was proposed to admit women who could not pay anything at all and also those who could afford to pay a small sum per week Until now there had been no place in London where poor women suffering from genito-urinary and allied diseases could be taken into hospital and treated for a small weekly payment Mr Gibbs made a special appeal for the gift of X ray equipment.

Air Force Accidents

Lord Gorell called attention to the frequency of accidents in the Royal Air Force He said that the Secretary of State for Air had said that there were 58 fatal accidents in the Force last year That was an average of more than one a week, and only in the previous week there were some more. The recent statement by the Prime Minister had not entirely removed all the sense of uneasiness on this question Most of these accidents occurred, as far as could be known, from certain definite causes He thought that it was admitted that the "stalling" of a machine, especially when it was near the ground, was at any rate a very frequent cause of these accidents He found among the technical experts criticism of the Air Ministry for having been rather dilatory in testing and possibly applying safety devices He did not associate himself with those criticisms, but he would like further information on the matter

The Duke of Sutherland (Paymaster-General), replying for the Air Ministry, said that from some criticism which had recently appeared in the Press, and had even been heard in the House of Commons, it might almost be supposed that the Air Ministry kept no proper record or statistics, but simply accepted the accidents as necessary concomitants of aviation It might even be supposed that the Air Ministry made no real endeavour to reduce the number of these accidents Nothing was further from the truth The Prime Minister had satisfied himself that the fullest statistics had been kept since the war, and that the whole problem was under constant review from every angle The Secretary of State and the Air Council had the very strongest motives for reducing the number of these accidents, if for no other reason than that such accidents were bound to act as a deterrent to recruiting The Prime Minister in his recent statement had shown conclusively that those accidents which were due to what he called remediable causes were a very small proportion of the whole, and that no particular type of machine, and no particular station or unit, was more prone to accidents than others It was a sad fact that aviation must for many years to come entail accidents The real question was whether the number could be successfully reduced—in other words, whether unnecessary and possibly avoidable accidents took place There was a constant improvement from 1921 to 1925 in the ratio of accidents to hours flown, whether fatal accidents, accidents involving injury to personnel, or accidents only causing material damage to machines The actual number of accidents irrespective of the amount of flying was not a fair basis of comparison, nor was the actual number of lives lost A comparison with other countries did not suggest that our accident rate was excessive In some respects—for instance, in accidents due to mechanical causes and maintenance—our record was a good deal better than other countries The Air Ministry was by no means content, however, with the improvement that had taken place Continual efforts to decrease the number of accidents were being made Short of crossing the psychological border-line, which as the Prime Minister had said would inevitably undermine the pilot's morale and destroy the fine spirit existing to-day, every precaution was taken Unnecessarily dangerous flying was forbidden and the prohibition was enforced Pilots were constantly under supervision both by senior officers and by the Royal Air Force Medical Service The Medical Service was fully alive to the necessity of detecting any incipient physical unfitness, strain, or staleness before harm could be done Abstemious habits, as far as possible, were enforced by regulation and inculcated by example In not one single case had indulgence in alcohol been proved to have caused or contributed to an accident in all the years covered by these statistics In the matter of design and research also efforts were being made towards greater safety

Lord THOMSON said, like everyone else who had been associated with the Air Ministry, he had lived rather under the shadow of this toll of human lives due to accidents He had had a certain experience of the psychology of our airmen when he was Secretary of State for Air One could not live with these lads for any length of time without noticing that some of them were very highly strung They were extraordinarily intelligent They had courage of the most remarkable kind, and in a way the more highly strung they were the better pilots they were in war and the better they were for this particularly dangerous sort of work A great many of them were reckless, and were rather like young thoroughbred horses, most difficult to handle They were a constant source of anxiety to those in charge of them, but no one denied that they were one of the glories of the race The men who trained our pilots had not only to have high professional qualities, but they also must have some of the qualities of a physician They were dealing with these highly strung young fellows, and they had to watch their health and their state of mind, for if either was at all defective at any given moment, that might make all the difference between a successful air evolution and a fatal crash It was in the interests of these men that they should be very chary about giving publicity to reports

TUESDAY, MARCH 29TH

Indian Medical Service

Lord LAMINGTON asked the Secretary of State for India what steps were being taken to reconstruct the Indian Medical Service and to provide adequately for the medical needs of the people of India?

The Earl of BIRKENHEAD said since this question was last raised in their lordships' House he had been in constant correspondence with the Government of India They in their turn had consulted the provincial governments in India with a view to constructing the future organisation of the medical service in India He had recently received from the Government of India their final proposals, and his comments on these were forwarded to them on Feb 17th Pending receipt of their reply he was not in a position to give to the House full details of the scheme which it was proposed to adopt The cardinal features of it were (1) the retention of the Indian Medical Service, and the necessary war reserve of trained medical men; (2) the provision of European medical attendance for European officers of the superior Civil Service and their families; (3) the creation of provincial medical services, recruitments for which would be carried out by the local governments themselves He anticipated that it would be possible to bring the new scheme into operation at no distant date

Sale of Food and Drugs Bill

On the motion of Lord LAMINGTON the Sale of Food and Drugs Bill was read a second time

HOUSE OF COMMONS

WEDNESDAY, MARCH 23RD

Vivisection

Lieut.-Commander KENWORTHY presented a petition signed by 15 286 inhabitants of London and other places praying that the practice of vivisection be prohibited by law

Cost of Beds in Military Hospitals

Sir FREDRIC WISE asked the Secretary of State for War the cost of a hospital bed per day and how it was approximately made up —Sir L WORTHINGTON-EVANS replied The estimated daily cost of each occupied bed is 13s 7d, of which 2s 9d is for the patient's maintenance, 7s 1d for staff, and 3s 9d for standing charges

THURSDAY, MARCH 24TH

Secretaries for School Medical Officers

Dr VERNON DAVIES asked the President of the Board of Education if he had received any reply from the Lancashire Education Authority with respect to his inquiry as to their provision of secretaries for school medical officers and, if so, had he come to any decision as to the necessity or otherwise for such appointments —Lord E PERCY replied I have received a report on this subject I understand that the 15 clerks employed as secretaries discharge a number of duties which, in other areas, fall upon the headquarters clerical staff and they are, therefore not to be regarded as a net addition to the staff required for the purposes of the School Medical Service I hardly think the Board are called upon to pronounce an opinion on the merits of minor administrative arrangements of this kind which must necessarily be left to the discretion of the authority

Feeding of Necessitous Children

Mr WESTWOOD asked the President of the Board of Education what was the State grant for feeding of necessitous children in England, and total expenditure for same, for the years 1922, 1923, 1924, 1925, and 1926 respectively, and what was the estimate for 1927 —Lord E PERCY replied The following is the information asked for The expenditure of local education authorities on the provision of meals in the financial years in question was as follows 1921–22, £951,000, 1922–23, £256 000, 1923–24, £152,000, 1924–25 £138,000, and 1925–26, £160,000 (pre-audit) The expenditure for 1926–27 cannot be ascertained until after the conclusion of the year As regards the coming financial year, the estimates of local authorities have not yet been received but, as at present advised, I anticipate that the expenditure will approximate to the normal Grant is not paid upon the separate items, but upon the whole, of an authority's expenditure on elementary education, of which expenditure on the provision of meals forms a small part

The Registration of Opticians

Mr ROBERT WILSON asked the Minister of Health whether he had decided to set up a committee to inquire into the question of registering opticians, and, if so would he state the terms of reference and the personnel of the committee —Mr CHAMBERLAIN replied The answer to the first part of the question is in the affirmative The terms of reference to the Committee will be to consider the Optical Practitioners (Registration) Bill and to make recommendations The personnel of the Committee is not yet quite complete, but I hope to be in a position to announce its composition at an early date

Mr R MORRISON May I take it that the Committee's terms of reference and their deliberations will be entirely confined to the question of opticians only?

Mr CHAMBERLAIN The Optical Practitioners (Registration) Bill is the one which they will consider

Mr H WILLIAMS Can the Minister of Health say whether the Committee is likely to report before May 13th, the date on which the Bill is set down for second reading?

Mr CHAMBERLAIN I do not think I am in a position to answer that question The Committee is only just being set up

Housing Conditions and Public Health

Mr DAY asked the Minister of Health whether, in view of the cost to the country caused by sickness owing to bad housing conditions, he will consider the introduction of legislation having as its object the licensing of all property owners who owned and let houses with a rateable value under £80 a year, so as to enforce an approved standard of sanitation and repair in these houses —Mr CHAMBERLAIN replied Local authorities already have wide powers under the Housing Act and Public Health Acts to secure

in Scotland; and, if so, when such legislation would be introduced —Sir John Gilmour replied I propose to await the Report of the Scottish Committee on Young Offenders which is now sitting, and to consider the two reports together I have already taken action on recommendations of the Committee which did not require legislation

Research Work and Tuberculous Milk

Mr Everard asked the Minister of Agriculture whether any research work was being carried out at present to endeavour to discover a quick and effective method of determining whether milk was tuberculous —Sir G Hennessy (Comptroller of the Household) replied I have been asked to reply on behalf of the Lord President of the Council as the subject falls within the scope of the Medical Research Council Various investigations have been promoted during the past few years in the attempt to devise better methods for the purpose One of these, undertaken jointly by workers at the National Institute for Medical Research and at the National Institute for Research in Dairying, made possible a considerable improvement of pre-existing methods An account of this was published in 1925 and I can give my hon friend the reference The subject is being kept in view, and further investigations will be made if new means of attacking this difficult problem can be found The reference to which I have referred is as follows S R Douglas and L J. Meanwell A New Method for the Concentration of Bacilli in Tuberculous Milk (*British Journal of Experimental Pathology*, 1925, vi, 203)

Roadside First-aid

Mr. Day asked the Minister of Transport if his attention had been drawn to the scheme of roadside first-aid that was being introduced by the British Red Cross Society and the Order of St John on the important arterial roads, and whether he would consider erecting special kiosks on the roadside to give the Society facilities for storing their equipment —Colonel W Ashley replied While welcoming any effort that may be made to render assistance to wayfarers, I am not in a position to incur expenditure on the erection of kiosks

Eyesight Tests for Motorists

Mr Day asked the Minister of Transport if he was aware that there were approximately 15,000,000 people in Great Britain who suffered with imperfect vision; and would he consider the introduction ,of legislation making it compulsory that all applicants for a motor-driving licence should pass a special eyesight examination, either by their own medical practitioner or competent optician, which should include tests for distance and colour vision, and produce a satisfactory certificate to the licensing authority before a driving licence was issued —Colonel W Ashley replied The draft Road Traffic Bill which has recently been published contains provisions for the withholding of a driver's licence from a person suffering from any physical disability (including defective vision) which is likely to cause the driving of a motor vehicle by him to be dangerous to the public The draft Bill also provides that in certain circumstances such a person may claim to be subjected to a test as to his fitness or ability to drive a motor vehicle

---

Messrs Baillière Tindall and Cox will publish on April 5th a book entitled "Lister as I Knew Him," by Dr J R Leeson, who is one of the few survivors who worked under Lord Lister in Edinburgh in the early days of antiseptic surgery The book will consist of 250 pages, with numerous illustrations and a portrait of Lord Lister

New Lodging-house for Women —The first Cecil House, to which reference was made in a leading article last week (The Lancet, March 26th, p 659) was opened by the Lord Mayor of London at 35, Devonshire-street, Theobald's-road, Bloomsbury, on March 28th The house has been acquired, adapted, and equipped at a cost of £3800, and contains 15 beds for which a charge of 1s a night will be made These are in nine rooms on three floors, the two smallest have each only one bed, and will be kept for women with babies The house has a comfortable sitting-room, a bath, and two foot-baths with a constant supply of water, and arrangements are made which allow lodgers to wash their clothes Besides these facilities, the fee of 1s includes tea and biscuits in the morning The house will be open every evening at 8, and though women may apply on consecutive nights they cannot secure accommodation in advance It is hoped that six lodgings of this kind will be opened in London, and since the campaign was started last October the sum of £8614 has been raised towards their establishment

Medical News.

University of Oxford —A Radcliffe Travelling Fellowship has been awarded to Mr Thomas Cecil Hunt B M Dr Hunt was an open scholar at Magdalen College he obtained the Theodore Williams Scholarship in Human Anatomy in 1922, the Theodore Williams Scholarship in Pathology in 1924, and the Radcliffe Scholarship in Pharmacology in 1924 —Mr Bernard Warren Williams, B M, F R C S Eng, has been elected to the Radcliffe Prize for a thesis on the Importance of Toxæmia due to Anaerobic Organisms in Intestinal Obstruction and Peritonitis Both Fellowship and Prize are in the gift of the Master and Fellows of University College

University of London —At a meeting of the Senate held on March 23rd the Vice-Chancellor, Sir William Beveridge, being in the chair, Mr W E Le Gros Clark, F R C S Eng, was appointed to the University Chair of Anatomy, and Dr Hamilton Hartridge, F R S, to the University Chair of Physiology, tenable at St Bartholomew's Hospital Medical School Both appointments will date from Sept 1st, 1927

Mr Le Gros Clark was appointed in 1924 to the University Readership in Anatomy, tenable at St Bartholomew's Hospital, and in the same year was awarded the Hunterian Medal for Anatomical Research and was elected a member of the Board of Examiners for the Fellowship of the Royal College of Surgeons of England In 1925 he was elected a member of the Prosectorial Committee of the Zoological Society and of the Council of the Anatomical Society

Dr Hartridge has been a Fellow of King's College, Cambridge, since 1912, and was awarded the Horton Smith Prize in 1918 Since 1919 he has been lecturer on Organs of Special Sense and Senior Demonstrator in Physiology at the Physiology Laboratories, Cambridge He has examined for the Universities of Cambridge and Sheffield

Society of Apothecaries of London.—At recent examinations the following candidates were successful in the undermentioned subjects —

Surgery —J De Rosa, London Hosp, J A Fernandez, St Bart 's Hosp, R Kahn and A M A. Moore, London Hosp R C Pratt, Birmingham, S Slotar, Guy's Hosp, and W G H. Warner, St Mary's Hosp

Medicine —G W Ayres, St Mary's Hosp

Forensic Medicine —G W Ayres, St Mary's Hosp, A C F Barrow, Edinburgh, L J Lawrie, London Hosp G C Rhys Jones Charing Cross Hosp, and H N Walker, St Bart 's Hosp

Midwifery —A C F Barrow, Edinburgh, W H Collins, London Hosp L J Corbett, St Mary's Hosp, S Goldman London Hosp, H H Lakin, Birmingham and London Hosp and W D Neill and S le R Switzer, London Hosp

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery G W Ayres, A C F Barrow, J De Rosa, R Kahn, and H N Walker

University of Liverpool —At recent examinations the following candidates were approved —

FINAL EXAMINATION FOR M B AND CH B DEGREES

Part I —R K Bowes (with distinction), Gladys A Coventr J H St B Crosby A Dala, H R Dugdale, R A Furnis K Jilani, E W Jones, Mary G Jones, T Lotter Hild M C MacMahon Garry, J S Mather, G W Molyneux Elizabeth B Robson, J L A Webster, and F J Welto

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY

G Friedland R W Gemmell, T Harrison, Agnes B MacGrego and A M Robertson

University of Aberdeen —At a graduatio ceremony on March 23rd the honorary degree of LL D was conferred on Prof Matthew Hay, Sir Frederick Gowland Hopkins, F R S, and Sir William Milligan The following degrees were also conferred —

M D —Philip Bayer (awarded commendation for thesis)

D Sc —Lieut -Colonel A G McKendrick, M B

M B, Ch B —*Wilfrid Marshall and *A S Paterson (with second class honours), G J Allan, A W Badenoch, John Barclay Catherine I A Craig J G H Davidson, R G Dingwall P T J Doss A D Duff G A P Fraser, J M C Gill John Leiper J W Lobban *N J R Logie *H G McPherson C P Mann, N G Marr J R. Moir J H Otty, Mary Riddoch, C C Ross, C G Walker, L G Walters

D P H —Jessie R G Dingwall John Innes

* Completed Final Medical Professional Examination with distinction

University of Glasgow —Among the recipients of the honorary degree of LL.D, to be conferred at the June Graduation will be Sir Charles Ballance, consulting surgeon to St Thomas s Hospital

Committee for Scientific and Industrial Research —The King in Council has appointed Mr Henry Thomas Tizard to be Secretary to the Committee of the Privy Council for Scientific and Industrial Research on the retirement of Sir H Frank Heath from that office on June 1st next

Society for the Study of Inebriety —The annual meeting of this Society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W, on Tuesday, April 12th, at 4 P M (tea and coffee at 3 45) Dr R W Branthwaite will open a discussion on the Inebriates Act of 1898

West Kent Medico-Chirurgical Society —A meeting of this society will be held at the Miller General Hospital, Greenwich, on Friday, April 8th, at 8 45 P M, when Dr H C Cameron will give an address on Common Neuroses of Childhood.

West End Hospital for Nervous Diseases The Savill (Memorial) Oration will be delivered by Dr Gordon M Holmes on Thursday, April 21st, at 5 P M., at the House of the Royal Society of Medicine, 1, Wimpole-street, London, W 1 Dr R Percy Smith will preside and the subject of the Oration will be Local Epilepsy The attendance of members of the profession and medical students is invited The hospital also announces that the Savill Prize (value £15) for a post-graduate thesis on a neurological subject will be awarded this year Particulars may be had from the Secretary

Royal Sanitary Institute —A sessional meeting will be held on Friday, April 8th, at 5 P M, in the Arts Theatre of the University, Liverpool, when a discussion on Rheumatic Affections in Children will be opened by Dr Dingwall Fordyce There will also be a discussion on the Liverpool Main Drainage System Dr G F Buchan will take the chair Those proposing to attend the session should notify Dr A A Mussen, Public Health Department, Municipal Buildings, Dale-street, Liverpool, not later than April 3rd

Lectures on Infant Care —Under the auspices of the National Association for the Prevention of Infant Mortality a course of lectures for health visitors, nurses, midwives, and superintendents of infant welfare centres will be given at the Infants Hospital, Vincent-square, Westminster, from 6 30 to 7 30 P M, on Mondays from April 11th to June 27th The lecturers include Dr C K Hamilton, Dr Eric Pritchard, Dr Henry MacCormac, Mr A H Todd, Dr A F Tredgold, Mr Philip Franklin, Dr C W Hutt, Dr Muriel Radford, and Dr Donald Paterson Tickets are obtainable from the Secretary of the Association at 117, Piccadilly, London, W

The Royal Association in aid of the Deaf and Dumb are shortly opening a small maternity home for the unmarried deaf and dumb mother and her child, the Home will be in London but deaf and dumb girls in need of such a home will be admitted from any part of England Mrs Campbell Dodgson held a meeting at 22, Montagu-square on March 24th in aid of this Home The Chairman, the Dean of St Paul's, and the two speakers, Miss Higson and Miss Spooner, emphasised the special need of these deaf and dumb girls and the impossibility of their receiving adequate help in the homes for the hearing They need the care of workers trained to understand them and whom they can understand, and this the Home will provide Contributions towards the Home will be gratefully received by the Treasurer, Royal Association in Aid of the Deaf and Dumb, 413, Oxford-street, W 1, and should be marked "Maternity Home"

Fellowship of Medicine and Post-Graduate Medical Association —The Fellowship is affiliated with some 50 hospitals in London which provide a general course of instruction Detailed information about their daily practice is supplied in diary form by the Fellowship and a comprehensive ticket for this general course is issued for any period from one week to one year, at a scale of fees ranging from 2 to 20 guineas, according to the period required. As the Easter vacation falls in the middle of April the special courses arranged for this month will not begin until the last week The Royal Waterloo Hospital will provide a comprehensive course in medicine, surgery, and gynæcology Lecture-demonstrations will be given by the staff in the wards and out-patient departments (fee £3 3s) A series of eight lecture demonstrations on tropical medicine will be given on Tuesdays and Thursdays at 2 P M. at the London School of Tropical Medicine beginning April 27th (fee £2 2s) Dr Heald will give a series of four lecture-demonstrations on successive Wednesdays at the Royal Free Hospital at 5 15 P M beginning on April 27th (fee £1 1s) Copies of all syllabuses and of the *Post Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

University of Adelaide —Dr H H Woollard Teacher of Anatomy at University College, London, has been appointed to be Professor of Anatomy at Adelaide University, in succession to Dr F Wood Jones

Royal Northern Hospital —A relatively small growth in the number of in-patients last year was accompanied by a large increase in the number of out-patients The X ray department is being rebuilt at a cost of £3000 The coal strike cost the hospital at least £1500

Cost of Hospital Treatment —According to the annual report of the Coventry and Warwickshire Hospital, the average cost of an in-patient last year was £6 16*s* 3*d*, an increase of 5*s* 3*d* on the preceding year Ten per cent of the deaths were in accident cases, and of the income of £40,000, £998 came from Approved Societies

Royal Victoria Hospital, Belfast —Last year, the first since the recent enlargement, the total number of patients increased by more than 4000, and on a recent day 1230 patients were treated The cost per bed has fallen by £14 Prof J A Lindsay has retired from the chairmanship of the board of management, and is being succeeded by the Marquis of Dufferin and Ava

New Zealand Mental Hospitals —The New Zealand Government has appointed to its mental hospitals department Dr H D Hayes, of Hanwell Mental Hospital, Dr J P Waters, neurological specialist to the Central Boards of the Ministry of Pensions in London, and Dr T W J Childs, Ministry of Pensions Mental Hospital, Kirkburton, Huddersfield

Royal Hospital for Sick Children, Glasgow —It is proposed to extend the country branch of this hospital at an estimated cost of £32,500 At the annual meeting it was intimated that only £10,000 more now remained to be raised in order to secure the gift of £17,500 from the trustees of the late Mr Peter Coats This is only one of many large hospital extensions now proceeding in Scotland, the demand everywhere is for increased hospital accommodation

An Overcrowded Portsmouth Hospital —The pressure, always serious, upon the accommodation of the Royal Portsmouth Hospital has lately been increased by the longer period during which patients are retained Thus on a recent day 26 of the 175 patients had been in the hospital for two months or more, and the average stay is half a day longer than in 1925 Had the average stay not been increased it would have been possible to receive 75 more patients, which practically represents the waiting-list

Birmingham and Midland Ear and Throat Hospital.—This institution is in urgent need of enlargement, but the present site will not permit of extensions, and proposals have been placed before the Hospital Council for its inclusion in the proposed Hospital Centre at Bournbrook Meanwhile the Ludgate Hill ward for children has been set aside for private paying cases The hospital has no X ray installation, and is spending £250 a year on sending out cases to have X ray photographs taken

Joint Tuberculosis Council —The Council has arranged for a post-graduate course on tuberculosis to be held in Copenhagen in May next Dr Axel Reyn has undertaken to arrange the course which will be largely of a clinical nature, members may look forward to seeing much of the work of the Finsen Institute, and there will be opportunities of visiting the various hospitals in Copenhagen Those attending the course will leave Harwich on Saturday, May 7th, and return to Harwich on Saturday, May 21st The approximate fare per person (for a party) will be £25, covering travel tickets, meals, hotel accommodation, and gratuities An application has been made to the Minister of Health to allow this course to rank for grant Further details may be had from the hon secretary, post-graduate courses, The Larches, Farnham Royal, Bucks

Complimentary Dinner to Dr Russell Andrews On March 22nd, at the invitation of Mr Comyns Berkeley, twenty eight personal friends met Dr Russell Andrews at the Garrick Club to bid him God speed on his retirement from practice The company included Dr J B Banister, Dr J D Barris, Dr E Bellingham Smith, Sir George Blacker, Mr Victor Bonney, Mr A W Bourne, Dr G Darwall Smith, Mr S Dodd Dr M Donaldson, Dr T W Eden, Dr J S Fairbairn, Dr J P Hedley, Mr. Eardley Holland, Dr Victor Lack, Dr S Gordon Luker, Sir Ewen Maclean, Dr A. C Palmer, Dr F L Provis, Mr L. C Rivett, Sir Henry Simson, Dr T G Stevens, Mr Clifford White, Dr J A Willett, Dr J M Wyatt, and Sir Hugh Rigby and Dr Lewis Smith, who joined the London Hospital in the same year as Dr Russell Andrews Dr Eden proposed in fitting terms the health, long life, and happiness of Dr Russell Andrews which was drunk with the greatest enthusiasm, after which Dr Russell Andrews replied in Scotland; and, if so, when such legislation would be introduced —Sir JOHN GILMOUR replied I propose to await the Report of the Scottish Committee on Young Offenders which is now sitting, and to consider the two reports together I have already taken action on recommendations of the Committee which did not require legislation

Research Work and Tuberculous Milk

Mr EVERARD asked the Minister of Agriculture whether any research work was being carried out at present to endeavour to discover a quick and effective method of determining whether milk was tuberculous —Sir G HENNESSY (Comptroller of the Household) replied I have been asked to reply on behalf of the Lord President of the Council as the subject falls within the scope of the Medical Research Council Various investigations have been promoted during the past few years in the attempt to devise better methods for the purpose One of these, undertaken jointly by workers at the National Institute for Medical Research and at the National Institute for Research in Dairying, made possible a considerable improvement of pre-existing methods An account of this was published in 1925 and I can give my hon friend the reference The subject is being kept in view, and further investigations will be made if new means of attacking this difficult problem can be found The reference to which I have referred is as follows S R Douglas and L J. Meanwell A New Method for the Concentration of Bacilli in Tuberculous Milk (*British Journal of Experimental Pathology*, 1925, vi , 203)

Roadside First-aid

Mr. DAY asked the Minister of Transport if his attention had been drawn to the scheme of roadside first-aid that was being introduced by the British Red Cross Society and the Order of St John on the important arterial roads, and whether he would consider erecting special kiosks on the roadside to give the Society facilities for storing their equipment —Colonel W ASHLEY replied While welcoming any effort that may be made to render assistance to wayfarers, I am not in a position to incur expenditure on the erection of kiosks

Eyesight Tests for Motorists

Mr DAY asked the Minister of Transport if he was aware that there were approximately 15,000,000 people in Great Britain who suffered with imperfect vision ; and would he consider the introduction ,of legislation making it compulsory that all applicants for a motor-driving licence should pass a special eyesight examination, either by their own medical practitioner or competent optician, which should include tests for distance and colour vision, and produce a satisfactory certificate to the licensing authority before a driving licence was issued —Colonel W ASHLEY replied The draft Road Traffic Bill which has recently been published contains provisions for the withholding of a driver's licence from a person suffering from any physical disability (including defective vision) which is likely to cause the driving of a motor vehicle by him to be dangerous to the public The draft Bill also provides that in certain circumstances such a person may claim to be subjected to a test as to his fitness or ability to drive a motor vehicle

As the Easter vacation falls in the middle of April the special courses arranged for this month will not begin *until* the last week. The Royal Waterloo Hospital will provide a comprehensive course in medicine, surgery and gynæcology. Lecture-demonstrations will be given by the staff in the wards and out-patient departments (fee £3 3s) *A series* of eight lecture-demonstrations on tropical medicine will be given on Tuesdays and Thursdays at 2 P.M. at the London School of Tropical Medicine beginning April 27th (fee £2 2s) Dr Heald will give a series of four lecture-demonstrations on successive Wednesdays at the Royal Free Hospital at 5 15 P.M. beginning on April 27th (fee £1 1s) Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London W 1.

UNIVERSITY OF ADELAIDE.—Dr. H. H Woollard Teacher of Anatomy at University College, London has been appointed to be Professor of Anatomy at Adelaide University, in succession to Dr. F Wood Jones.

ROYAL NORTHERN HOSPITAL.—A relatively small growth in the number of in-patients last year was accompanied by a large increase in the number of out-patients The X ray department is being rebuilt at a cost of £3600 The coal strike cost the hospital at least £1500

COST OF HOSPITAL TREATMENT.—According to the annual report of the Coventry and Warwickshire Hospital, the average cost of an in-patient last year was £6 16s 3d, an increase of 5s 3d on the preceding year Ten per cent. of the deaths were in accident cases, and of the income of £10,000, £998 came from Approved Societies

ROYAL VICTORIA HOSPITAL BELFAST.—Last year the first since the recent enlargement, the total number of patients increased by more than 4000, and on a recent day 1230 patients were treated. The cost per bed has fallen by £11. Prof J. A Lindsay has retired from the chairmanship of the board of management and is being succeeded by the Marquis of Dufferin and Ava

NEW ZEALAND MENTAL HOSPITALS.—The New Zealand Government has appointed to its mental hospitals department Dr H. D. Hayes, of Hanwell Mental Hospital; Dr J P Waters neurological specialist to the Central Boards of the Ministry of Pensions in London; and Dr. T W J Childs, Ministry of Pensions Mental Hospital, Kirkburton, Huddersfield

ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.—It is proposed to extend the country branch of this hospital at an estimated cost of £32,500 At the annual meeting it was intimated that only £10,000 more now remained to be raised in order to secure the gift of £17 500 from the trustees of the late Mr Peter Coats This is only one of many large hospital extensions now proceeding in Scotland the demand everywhere is for increased hospital accommodation.

AN OVERCROWDED PORTSMOUTH HOSPITAL.—The pressure, always serious upon the accommodation of the Royal Portsmouth Hospital has lately been increased by the longer period during which patients are retained Thus on a recent day 26 of the 175 patients had been in the hospital for two months or more, and the average stay is half a day longer than in 1925 Had the average stay not been increased it would have been possible to receive 75 more patients, which practically represents the waiting-list.

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL.—This institution is in urgent need of enlargement, but the present site will not permit of extensions, and proposals have been placed before the Hospital Council for its inclusion in the proposed Hospital Centre at Bournbrook. Meanwhile the Ludgate Hill ward for children has been set aside for private paying cases The hospital has no X ray installation and is spending £250 a year on sending out cases to have X ray photographs taken

JOINT TUBERCULOSIS COUNCIL.—The Council has arranged for a post-graduate course on tuberculosis to be held in Copenhagen in May next. Dr. Axel Reyn has undertaken to arrange the course which will be largely of a clinical nature, *members may look* forward to seeing much of the work of the Finsen Institute, and there will be opportunities of visiting the various hospitals in Copenhagen Those attending the course will leave Harwich on Saturday, May 7th, and return to Harwich on Saturday, May 21st The approximate fare per person (for a party) will be £25, covering travel tickets, meals hotel accommodation and gratuities An application has been made to the Minister of Health to allow this course to rank for grant. Further details may be had from the hon secretary, post-graduate courses The Larches, Farnham Royal, Bucks.

COMPLIMENTARY DINNER TO DR RUSSELL ANDREWS On March 22nd, at the invitation of Mr Comyns Berkeley, twenty-eight personal friends met Dr Russell Andrews at the Garrick Club to bid him God speed on his retirement from practice. The company included Dr J. B. Banister, Dr. J D Barris, Dr E Bellingham Smith, Sir George Blacker, Mr Victor Bonney, Mr A. W. Bourne, Dr. G Darwall Smith, Mr S Dodd. Dr. M. Donaldson, Dr. T. W Eden Dr. J S Fairbairn, Dr J. P. Hedley, Mr. Eardley Holland, Dr. Victor Lack, Dr S Gordon Luker, Sir Ewen Maclean Dr A. C. Palmer, Dr. F L. Provis, Mr. L. C Rivett Sir Henry Simson, Dr. T. G. Stevens Mr. Clifford White. Dr J A. Willett Dr J M Wyatt, and Sir Hugh Rigby and Dr Lewis Smith who joined the London Hospital in the same year as Dr Russell Andrews. Dr. Eden proposed in fitting terms the health, long life, and happiness of Dr Russell Andrews which was drunk with the greatest enthusiasm, after which Dr. Russell Andrews replied.

MEDICAL GOLFING SOCIETY —The Knock-out Tournament of this society has now reached its semi-final stage, which will be played by J Cunning, J Everidge, E Playfair, and E N Plummer

CONFERENCE ON VIVISECTION —The British Medical Association is calling a conference, to be held at its house in Tavistock-square, London, on April 4th, with the object of showing what attitude is taken up by medical and allied bodies on the subject of vivisection

TYPHOID FEVER EPIDEMIC —It is reported that an epidemic of typhoid fever has broken out in the Newmill and Holmfirth district of the Holme Valley, near Huddersfield Thirteen cases have occurred at Newmill and six at Holmfirth

LISTER CENTENARY AT PHILADELPHIA — On April 6th *a meeting of the College of Physicians of Philadelphia* will be held to celebrate the centenary of Lord Lister Addresses will be given by Sir Esme Howard, the British Ambassador to Washington, and by Mr Astley P C Ashhurst, surgeon to the Episcopal Hospital

FRESH AIR SCHOOL AT GRIMSBY —A new council school, which has cost approximately £22,000, was opened at Victoria-street, Grimsby, on March 24th It is so constructed that in fine weather practically the whole of the building can be thrown open to the fresh air It has accommodation for 300 girls and 250 infants

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole street, W

MONDAY, April 4th —8 30 P M, SOCIAL EVENING

TUESDAY —5 30 P M, ORTHOPÆDICS (Cases at 4 30 P M) Mr R C Elmslie Two cases of Spastic Paralysis Associated with Scoliosis Mr Alan Todd Case of ? Periostitis of Metatarsal Other cases will be shown

WEDNESDAY, April 6th —8 P M, ODONTOLOGY, DISEASE IN CHILDREN Special joint discussion Oral Manifestations of General Disease in Children Openers Mr A T Pitts (Odontology) Dr Robert Hutchison (Disease in Children)

WEDNESDAY —8 P M (for 8 15 P M), TROPICAL DISEASES AND PARASITOLOGY Laboratory meeting at the London School of Hygiene and Tropical Medicine, 23, Endsleigh gardens (Euston-square) W C 1 Paper Prof W Robinson Some Features of Crown Gall in Plants in Reference to Comparisons with Cancer This will be followed by a demonstration of laboratory exhibits illustrating crown gall and recent developments in tropical diseases and parasitology

THURSDAY —5 P M, GENERAL MEETING OF FELLOWS Special Discussion on Bloodletting Opening speakers Mr Walter G Spencer, Dr Herbert French, Dr *Fortescue Fox*

FRIDAY —5 P M, LARYNGOLOGY (Cases at 4 P M) Cases and Specimens will be shown by Mr J A Gibb, Mr Harold Kisch, Dr T B Jobson, Mr T B Layton, Mr A J Hutchison, Dr A L Macleod, Mr Norman Patterson 8 30 P M, ELECTRO THERAPEUTICS Papers Prof S Russ and Miss G M Scott The Growth of Tumours in Tissues exposed to X Rays and Radium The Action of Radon Seeds upon Tumours and Some Normal Tissues of the Rat Dr J C Mottram On the Co-relation Between the Experimental and Clinical Radiation of Tumours

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W C

MONDAY, April 4th —5 P M, Mr C E Shattock Large Intestine

FRIDAY, 5 P M, Prof Sir Arthur Keith The Anatomy and Physiology of the Cæcum and Appendix Vermiformis

HOSPITAL FOR SICK CHILDREN, Great Ormond street, W C

THURSDAY, April 7th —4 P M, Dr Pearson Vomiting in Pregnancy

NORTH EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N

MONDAY, April 4th —10 A M, Surgical Clinic 2 P M, Medical Cases in the Wards 2 30 P M to 5 P M, Medical, Surgical and Gynæcological Clinics Operations

TUESDAY —2 30 P M to 5 P M, Medical, Surgical, Throat, Nose, and Ear Clinics Operations

WEDNESDAY —2 30 P M to 5 P M, Medical, Skin, and Eye Clinics Operations

THURSDAY —11 30 A.M., Dental Clinic 2 30 P M to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics Operations

FRIDAY —10 30 A M, Throat, Nose, and Ear Clinics 2 30 P M to 5 P M, Surgical, Medical, and Children's Diseases Clinics Operations

Also on FRIDAY, April 8th, at 4 30 P M, Dr L R Yealland will demonstrate on Selected Cases of Nerve Disease

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole street, W

MONDAY, April 4th, to SATURDAY, April 10th —QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E All day course, the chief feature of which is the showing of cases ROYAL EYE HOSPITAL, Southwark, S E Afternoon demonstrations on the diagnosis and treatment of diseases of the eye Further information from the Secretary

PEOPLE'S LEAGUE OF HEALTH (Sims Woodhead Health Lectures)

MONDAY, April 4th —6 P M (at the Medical Society of London, 11, Chandos street, W), Dr H Crichton Miller Development and Function of Mind

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn road, W C

FRIDAY, April 8th —4 P M, Dr Andrew Wylie Tuberculosis of the Larynx

ST MARGARET'S HOSPITAL FOR WOMEN, Acomb street, Whitworth Park, Manchester

WEDNESDAY, April 6th —12 noon, Mr A C Magian *Ovarian Grafting* demonstration

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES

TUESDAY, April 5th —4 15 P M, Dr C H Melland Epidemic Encephalitis, Acute and Chronic

FRIDAY —4 15 P M, Dr A Ramsbottom Demonstration of Medical Cases

ST MARY'S HOSPITALS, MANCHESTER POST-GRADUATE LECTURE

FRIDAY, April 8th —4 30 P M (at the Whitworth street West Branch), Dr W R. Addis Induction of Labour

ANCOATS HOSPITAL, POST GRADUATE LECTURES, Mill-street, Manchester

THURSDAY April 7th —4 15 P M, Dr W J S Reid Tabes *Dorsalis*

Appointments.

SOURASKY, M, M D Leeds, F R C S Edin, has been appointed Assistant Surgeon in the Ear, Nose, and Throat Department of the London Jewish Hospital

Certifying Surgeons under the Factory and Workshop Acts VINES, S K, L R.C P Edin, L M R C P I (Allendale), WELLS, J, M R C S, L R C P Lond (Bilston) KEITH, F L, M D Aberd Medical Officer of Health of Bethnal Green

Vacancies.

For further information refer to the advertisement columns

Beit Memorial Fellowship for Medical Research —Fellowships

Belgrave Hospital for Children, Clapham road, S W —Hon Radiologist 50 guineas

Birmingham and Midland Eye Hospital —Res Surg O £150

Cambridge, Addenbrooke's Hospital —H S At rate of £130 Also Cas O and Res Anæsthetist At rate of £130

Canterbury, Borough Mental Hospital —Asst M O £300

Charing Cross Hospital Institute of Pathology, 62–65, Chandos street Strand, W C —Asst Pathologist £500 for first six months

Chester Royal Infirmary —H S £150

Derbyshire Royal Infirmary, Derby —H P and Asst H S, and Cas O Each at rate of £150

Dover, Royal Victoria Hospital—H S £180

Exeter, Royal Devon and Exeter Hospital —Res Cas O At rate of £100

Gravesend and North Kent Hospital —Jun H S £150

Grimsby and District Hospital —Sec Supt £300

Guildford Royal Surrey County Hospital H S £150

Halifax Royal Halifax Infirmary —Third H S £100

Hampstead General and North West London Hospital, Haverstock Hill, N W —H S, H P, and Cas M O Each at rate of £100

Hospital for Consumption and Diseases of Chest, Brompton S W —H P

Hospital for Epilepsy and Paralysis, Maida Vale, W —Res M O and H P At rate of £150 and £100 respectively Also Hon. Gynæcologist
Leeds, Gateforth Sanatorium —Res M O £400
Leicester Royal Infirmary —Hon S to Ear, Nose, and Throat Dept
Manchester, Ancoats Hospital —H S for Orthopædic Dept At rate of £100
Manchester Royal Infirmary —Res Surg O £200
Manchester Victoria Memorial Jewish Hospital, Hon Surg Also Sen. H S £250
Manor House Hospital, Golders Green, N W —H S At rate of £200
Metropolitan Hospital, Kingsland road, E —H P 's , H S 's , and Two Cas O 's At rate of £100
Mount Vernon Hospital for Diseases of Chest, Northwood, Middlesex —Asst Res M.O At rate of £250
Northumberland County Council and Urban District Council of Newburn —Asst County M O H , &c £700
Norwich, Norfolk and Norwich Hospital —H S £120
Perth, James Murray s Royal Asylum —Asst P £300
Portsmouth, St Mary s Infirmary, &c —First Asst Res M O £350
Prince of Wales's General Hospital, Tottenham, N —Two Hon Anæsthetists Each £40
Princess Louise Kensington Hospital for Children, N Kensington —One P , Two Asst. P 's, Two S 's and Two Asst S 's &c
Putney Hospital , Lower Common, Putney S W —Res M O £150
Redhill, Surrey, Royal Earlswood Institution —Jun Asst M O At rate of £250
Richmond Royal Hospital —Asst H S At rate of £100
Royal Chest Hospital, *City road, E C* —H P At rate of £100 Also Res M O At rate of £150
St Albans Herts, Hill End Mental Hospital —Third Asst M O and Pathologist. £450
St John's Hospital, Lewisham, S E —Res Cas O At rate of £100
Sheffield Royal Infirmary —H S At rate of £80
Stockton on-Tees Stockton and Thornaby Hospital —Hon S to Ear Nose and Throat Dept
University of London, South Kensington, S W —Chair of Anatomy, £1000
Ventnor, Isle of Wight Royal National Hospital for Consumption —Med. Supt £1000
Walthamstow, Wanstead, and Leyton Children's and General Hospital —Sen. Res H S and Jun Res H S At rate of £150 and £100 respectively
Weir Hospital Grove road, Balham, S W —Jun Res M O £100
West End Hospital for Nervous Diseases, 73, Welbeck-street, W —Cas P £200

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons Matlock (Derbyshire, Buckhaven (Fifeshire), and Sedbergh (Yorks, West Riding)

Births, Marriages, and Deaths.

BIRTHS

CHEYNE.—On March 22nd at Quinton Lodge Leamington Spa, the wife of Dr A. L. Cheyne of a son (stillborn)

COXON —On March 22nd, the wife of Cedric Coxon, M.B , Dersingham, of a son

DAVIES —On March 20th, at Tavistock House, Haywards Heath, the wife of Dr J H Twiston Davies, of a son

LEAK.—On March 22nd at Dingle House, Winsford Cheshire, the wife of Dr W Norman Leak of a son (John)

SCHLESINGER.—On March 26th at Hollycroft-avenue, London, the wife of Dr Bernard Schlesinger of a daughter

MARRIAGES

CRESWELL—TURTON —On Jan 15th, at Vryheid, Natal, Harry Edmund Creswell M.C , M.B , B Ch. Cantab , M.R.C S Eng , M.R.C P Lond., to Amy Joyce, youngest daughter of the late Frank Turton, Esq of Hayfields, Glencoe, Natal

PATERSON—GIBSON —On March 22nd, at Christ Church, Bournemouth Archibald Richard Paterson, M D , to Gladys Violet, youngest daughter of the late Edward Gibson, of Parkstone

DEATHS

BROWNLEE.—On March 20th at Spencer-road Twickenham, Dr John Brownlee, M.D , D P H , Statistician to the National Medical Research Committee

HASLAM.—On March 15th, at St. Winnows Bromley, Kent Arthur Charles Haslam, aged 54

POLLARD —On March 21st, at his residence, Upper Hamilton-terrace Joseph Pollard, M.A., M.R.C S

STOVIN —On March 20th, very suddenly at a nursing home, Yeovil, Somerset, Cornelius Frederick Stovin, M A. Oxf , L S A. D P H., aged 64

WHITE.—On March 21st, at Rake's Halt Cove, Bampton, Devon, Colonel William Westropp White, C B , C.M G , M.D , I.M.S (retired) aged 64

WONNACOTT —On March 22nd suddenly, at Neville-court, Grove End-road, N W , R. R. Howard Wonnacott, M.R.C S , L R.C.P , aged 60

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Comments, and Abstracts.

THE CHRONIC RHEUMATIC DISEASES *

BY CAREY F COOMBS, M D , F R C P LOND ,
PHYSICIAN WITH CHARGE OF OUT PATIENTS, BRISTOL GENERAL HOSPITAL.

BETWEEN the various maladies which may still be included within the omnibus title of Chronic Rheumatic Diseases there is more diversity than similarity The one thing common to them all is pain limiting and interrupting the movements of the limbs and trunk. That is what the patient complains of, and as the first rule of treatment is to remove the cause, it follows that ever since patients began to complain of rheumatic pains physicians have been searching for causes In many instances these have been found, and certain categories of articular crippling have been lifted wholesale out of the general assemblage of disorders labelled rheumatic For example, there are the arthropathies that accompany organic disease of the central nervous system such as locomotor ataxia, and those other crippling changes in joints that may arise as a result of chronic infections of the lung

No well informed person would nowadays think of describing these as rheumatic Then there are other orders of articular disease which are emerging from the rheumatic pool Let us glance for a moment at two of these—chronic gout and gonococcal arthritis The first point of similarity between them is that each possesses its own peculiar symptomatology, although in each case the clinical picture may so far imitate others that what may be termed the hedging titles, "rheumatic gout" and "gonorrhœal rheumatism," are still employed, even by those who ought to know better

The second point is that in each instance the discernment of a clinical individuality, that of chronic gout on the one hand and of gonococcal arthritis on the other, has made it easier, one might almost say made it possible to discover behind the characteristic clinical picture a definite causation In the case of gout we have a disorder of the internal chemistry, with a strong hereditary factor and an even stronger connexion with certain forms of dietetic excess Gonococcal arthritis, on the other hand, is due, as its name indicates, to a generalisation throughout the body of the specific microbe of gonorrhœa

A third and highly significant point of similarity between these two diseases is the fact that both of them are decreasing in frequency This decrease has been due, not to an organised campaign against gout on the one hand or gonorrhœal arthritis on the other, but rather to a recognition, first by the medical profession and then by the public, of these ætiological facts , and also to an increasing respect for dietetic temperance in the one case, and for chastity in the other

This, then, has been the series of steps by which the incidence of certain forms of arthritis has been reduced First, the clinical type has been defined Second, the causation of the group has been sought and found Third, diffusion of the knowledge of this causation has led to its prevention Can we make use of a similar process in order to get rid of other forms of "rheumatic" disorder?

Clinical Aspects

Let us look first of all at the clinical aspects of these disorders to see whether there is any hope of grouping them, and thus of taking the first step in tracking down their causes It is here that the report of the Ministry of Health, to which I alluded last week, comes once more to our aid The Committee to whom we owe that report surveyed the various classifications of rheumatic disease and eventually adopted one which recognised three main groups With one of these, acute rheumatism, we concerned ourselves last week, and have, therefore, no need to discuss it further The other two were the non-articular forms of rheumatic disorder and the chronic joint diseases These, again, were subdivided, and under the latter heading were arrayed rheumatoid arthritis, osteo-arthritis, gout, and unclassifiable lesions of joints Of these four subdivisions we have already discussed one, that of gout Another, the group of unclassifiable lesions, need not detain us, since it is obvious that our studies of causation should end in its complete disappearance This leaves two large and well-defined groups of chronic articular disease for our consideration Of these two it will be convenient to approach the rheumatoid group first; for it is the one more nearly allied to acute rheumatism, a disease of whose causation we know a good deal, so that we may hope to be able to reason from the known to the unknown, from the causation of the acute rheumatic infection to that of rheumatoid arthritis

---

* Lectures on the Causes and Prevention of Rheumatism delivered under the Chadwick Trust The first lecture appeared in two instalments in THE LANCET of March 12th and 19th The second lecture (of which this is the first half) was given on March 10th, 1927

Rheumatoid Arthritis

This malady begins to claim its victims about the age of 20 and continues to do so throughout life, as the attack-rates of the Ministry of Health's inquiry show It is, according to Strangeways, three times as common in women as it is in men *Its symmetrical distribution is characteristic* and highly suggestive of some generally diffused cause It attacks the small joints, *for* example *those of the hands,* before it does the large ones The changes which it induces are limited, at first at all events, to the synovial membranes and the soft parts surrounding the joints, the bones themselves being free from change till late in the disease Its course, though tending to be progressive, is capable of arrest, and even when it progresses does so in bouts of activity separated by long periods of quiescence In its selection of young subjects, and its preference for women, this disease is similar to the acute rheumatic infection. Many of its bouts of activity are febrile, and in this as well as in other respects the similarity to an acute or subacute outbreak of rheumatic infection may be very close Occasionally, though not so often as we might expect, perhaps, cardiac disease develops in the patient with rheumatoid arthritis Of very great significance is the fact that subcutaneous nodes occasionally develop in rheumatoid arthritis These nodes, as Vincent Coates and I have shown, are exactly similar in structure to those of the rheumatic infection of childhood, and, as we saw last week, the subcutaneous node of that infection is its most individual achievement Nothing could suggest more strongly than this does that the same kinds of organisms that are responsible for the rheumatic infection of childhood are also responsible, in some cases at any rate, for causing rheumatoid arthritis There is, therefore, a good deal of reason for expecting to find the causation of rheumatoid arthritis somewhere near that of the rheumatic infection

Now we have seen that in many instances the rheumatic infection appears to be the diffused and general expression of a tonsillar sepsis This analogy has given direction to the search for causes of rheumatoid arthritis, and has lent support to a belief in the view recently crystallised in the name "focal arthritis" which my friends Drs Thomson and Gordon of Bath propose to apply to what is generally called rheumatoid arthritis Briefly, the theory enshrined in this term is one which regards the joint changes of rheumatoid arthritis as resulting from repeated doses of micro-organisms, or their toxins, escaping *into the circulation from* some focus of infection which contains and imprisons them only imperfectly Foci of this kind are especially sought for, and in variable percentage found, in the accessible parts of the respiratory and digestive tracts, in the nasal accessory sinuses, the tonsils, and the teeth

Now, if this were all, the treatment of rheumatoid arthritis would be no great matter Get rid of oronasal sepsis and you would eradicate rheumatoid arthritis But a very brief experience *of this train of thought will display its limitations* The woman whose articular changes progress in spite of a liberal application of this policy, involving removal *of all her teeth and a good deal of* her nose, is by no means rarely encountered It is quite obvious that there are other intermediary influences which determine whether a focus *of sepsis shall or shall not be able to* inflict its products on its victim's joints, and thus provoke a rheumatoid arthritis This is proved, not only by the failure of radical treatment *of sepsis to prevent* arthritis, but also by the failure of untreated sepsis to cause it The world is full of people with streptococci imprisoned within their nasal sinuses or at the apices of their teeth, yet with no lesion of joints Moreover, how is it that in one patient the escape of streptococci from the mouth into the circulation causes rheumatoid arthritis, but in another a persistent and progressive infection of the valves of the heart? Is not the very fact that the incidence of this arthritis is so much heavier in women, a strong hint of the presence of some deep-seated biochemical influence? That other streptococcal lesion to which I have alluded—a progressive infection of the cardiac valves, or endocarditis lenta—fell, just after the war, with unusually heavy weight, on young men, and this was found to be due to a predilection for ex-soldiers *This again* appeared to be traceable to the abnormal fatigue of certain forms of military service, to something, that is *to say,* which altered the chemistry of the body Is it not probable that the peculiar affinity between rheumatoid arthritis and women in early middle life is also a chemical affinity? Dr Llewellyn thinks we shall find a relation between thyroid aberrations and the rheumatic diseases, the suggestion being that a disturbed thyroid secretion may so alter the chemistry of the body as to lay it *open to the assaults of microbes that* would otherwise fail *to* inflict damage Again, there is reason to suppose that a series of links in the chain that joins the original focus with its arthritic consequences is *to be* found in some peculiarity in the immunity reactions of the susceptible individual I hesitate even to name this possibility, so vague and impalpable is it Yet the similarity between the joint affections of serum sickness on the one hand, and those of subacute rheumatism and the acuter phases of rheumatoid arthritis on the other, and the favourable effect of introduction *of foreign* proteins into the body, in a controlled dosage, in some cases of rheumatoid arthritis, and many other such considerations, *encourage a belief that some form* of sensitiveness to unfamiliar albuminous substances is essential to the causation of rheumatoid arthritis We have to bear in mind how closely similar are the reactions of the skin and mucous membranes on the one part, and of the synovial membranes of the joints on the other, to the introduction of foreign substances of this class

In the whole group of exudative phenomena, ranging from nettle rash to hæmophilia through every shade and degree *of purpura,* that which happens in the mucous membranes and skin happens also in the joints, and many of these outbreaks we know *to be due to the escape of foreign proteins,* bacterial or otherwise, into the circulation As an example I might quote the case of a young married woman who was recently under my care in the Bristol General Hospital I first saw her in the latter part of 1925 because of recurrent attacks of swelling and stiffness in the knee-joints These attacks would begin quite suddenly and then disappear gradually in the course of *a* few days I arranged to take her into the hospital wards for investigation, but something intervened to prevent this, and I *saw no more of* her for about a year Then she was sent up again, this time on account of recurrent swelling of the face, of the kind known as giant urticaria or angioneurotic œdema On examining her throat I found both tonsils shrunken, and a long sinus in the right tonsil from which pus could be squeezed From this pus a streptococcus was grown, and an emulsion of the culture was inoculated into her scarified skin, which showed a definite sensitiveness to the test My colleague, Mr John Wright, removed both tonsils very carefully and thoroughly, and it is interesting to note that this was followed immediately by a rise of temperature and a brief bout of swelling, just in that part of the face in which the urticaria had been wont to appear, and then in the knee-joints These phenomena soon passed off, but do they not suggest that operation *did,* for the moment, release into the circulation toxins akin to those which had already provoked similar attacks?

I have allowed myself to go far afield in pursuit of these *fascinating* speculations because I want to suggest that until we have at least attempted to solve the problem of the links that join the primary focus of infection with the arthritis itself, we have no right to content ourselves with the view that there is nothing to be done save the uprooting *of those foci And, indeed, there are other reasons for* caution First it is by no means always easy to be sure where the causal focus lies *Even if the teeth sockets are* infected, is it here that the *organisms* get in? Is it not possible that they are entering through the intestinal wall also? Is not this one explanation of the frequency with which removal of infected teeth fails to arrest the progress of an arthritis? Again, most of us can recall cases in which the progress of the disease appeared to be actually hastened by extraction of teeth or operations on sinuses, because the exposure of defenceless tissues to the causal microbes *made it easier for those microbes to enter* the beleaguered body And in any case the loss of teeth or tonsils is a misfortune which can only be inflicted on a patient if we are able to promise some overtopping advantage

I wish there were opportunity to discuss the part played by faults in the less accessible regions of the alimentary and respiratory tracts, in the causation of rheumatoid arthritis It would serve to emphasise *the need* that I have tried to make plain, of more research into the nature of the idiosyncrasies which render certain persons liable to develop rheumatoid arthritis as a consequence of focal sepsis, while others equally infected *remain nevertheless* immune

Osteo-arthritis

The second subdivision of the chronic joint group of *the Ministry of Health report* is labelled osteo-arthritis The joint troubles that belong to this category are quite different from those of the rheumatoid arthritis group They are seen in old people, much more often in men than in women, they tend to localise themselves in one joint rather than in many, *and* in big joints rather than small ones, and the lesion is one of bone rather than of synovial membrane In all these points osteo-arthritis presents a complete contrast to *rheumatoid arthritis and on* the whole this contrast is a true one, save for shades of compromise between the two groups to which I *shall allude* presently It is a remarkable thing that the joints should be liable to two types of crippling disease, widely dissimilar, yet alike in so far as joints are attacked by some progressively crippling disorder in both We are constrained to ask why joints should be so much more liable to permanent disablement than muscles or bones are; for there is, apart from injury, scarcely any common form of progressive crippling that is concentrated in either of these structures

The question of vulnerability of certain tissues is one which usually provokes two sorts of answers There is the anatomical explanation which blames the exposed position of the affected part for getting it into trouble and the physiological, which ascribes the liability of a tissue to disease to some delicacy or incessancy of function by which its cells are rendered easier to injure. In the case of the joint the anatomical view would suggest that the blood-supply of the part is responsible For one thing, the joints are end-points in the circulation Around them the blood-vessels of the limb come to an end in branches which unite with each other to form anastomoses This explains the predilection of the exudative lesions of urticaria purpura, and so forth for the neighbourhood of joints and is in part responsible for the concentration of the subcutaneous node of rheumatic infection in the same region. Again, the blood passing through the synovial fringes of the joint must perforce move slowly since the capillaries are looped sharply on themselves As Dr Scott Williamson once pointed out to me, this favours the escape of bacteria and toxins from the blood as it creeps sluggishly through capillaries of the membranes lining the joints Physiologically, also the joints are vulnerable structures, for they are continually bearing the brunt of the shocks and jars to which the limbs are necessarily subjected They are the buffers which interpose between one segment of a limb and the next and it is not wonderful, therefore, that after decades of use and abuse they should often manifest evidences of wear and tear This is without doubt responsible in large part for the lesions of osteo-arthritis, just as the anatomy of the parts is largely responsible for the selection of joints rather than other tissues, by the organisms and toxins that cause rheumatoid arthritis

This is not to deny the possible existence of an infective factor in osteo-arthritis Quite apart from the gross evidences of infection which can occasionally be discerned in persons suffering from osteo-arthritis, it is probable that as we grow older we gradually lose our capacity for protecting ourselves against the bacteria that our bodies entertain You will recollect that Metchnikoff sought thus to explain the nature and distribution of the arterial changes that characterise advancing age, and if we reflect for a moment on the area exposed in the alimentary and respiratory tracts to the bacteria that infest them, we shall marvel more at the defence that the body maintains against them than at the injuries which they succeed in inflicting Probably their toxins have a share in destroying the integrity of the joint, and the fact that both osteo-arthritis and arterial degeneration are diseases of the later decades of life may be regarded as the expression of a progressive decrease in the power of the body to resist the onslaughts of the bacteria that it carries If we admit this, we recognise that the predominant partner in this plot against the bodily well-being is age. We are familiar with the fact that in general, infections claim their victims most easily from the two extremes of life; from infants and young children because they have not yet learnt the art of self-defence, from old people because they are losing that art If we are asked by what mechanism this progressive reduction in the capacity to resist infection is brought about, we can only reply in general terms that the infant develops from the germ-cells by virtue of an inherent vital energy that, after he has entered on an existence separate from that of his mother still continues for approximately one-third of his natural life to provide the impetus for growth, that this same energy appears able for the next third of his career, to make good most of his tissue losses; but that during his final third he is no longer able to do so Cells wear out and disappear, but no new ones grow up to take their place. So it is with the component parts of his joints It is the duty of these to bear the shocks and jars to which the human frame is subjected. As age advances decreasing muscular power exposes the joints more and more to those minor injuries, every one of which must involve some destruction of the articular tissues Moreover, as we have seen, the tendency of bacterial activity is to flourish more readily as advancing age furnishes a less effective opposition. On the one hand, then the joint tissues are being more readily damaged, on the other, less effectively repaired

What can preventive medicine do to oppose this combination of injuries? Very little, it must be confessed. Neither Act of Parliament nor any other human agency can postpone appreciably that failure in the vital energy that is the chief root of the trouble. It may be that some future generation will discover the elixir of life, and taste the joys of a protracted sojourn in the flesh, but we cannot as yet point to the smallest evidence of this, while all that we know of the past history of mankind discourages any expectation of a sensible increase in the average duration of a lifetime

Let us return from these airy speculations to the solid ground of everyday practice, and take stock of the man who is a likely subject for osteo-arthritis He is 60 years old, he has worked hard at some manual task, his teeth are few and evil; his bronchial tubes are permanently infected; his subcutaneous tissues are shrinking and so are his muscles Which line are we to take? Must he submit to the removal of his teeth and to incessant attempts, foredoomed to failure, to make an end of his bronchial catarrh by the use of vaccines and other bactericidal devices? Or is the stress to be laid on an adequate supply of good air and light, with a temperate balance between work and rest? For it seems to me quite certain that too little exercise is almost as provocative of osteo-arthritis as too much The man who allows his earliest experiences of pain in a shoulder to inhibit all movement of the arm is laying down permanent changes in that joint as surely as the man who is prompted by circumstances or temperament to ignore his pain entirely The fact is that in the handling of osteo-arthritis, whether from the preventive or from the remedial aspect, there is ample room for common sense, but not for much else Of all these chronic rheumatic troubles it is true, I believe, that more harm is being done by too much treatment than by too little

(To be concluded.)

THE THERAPEUTIC VALUE OF IODINE

WE have received from Dr E T Burton of Clevedon, a series of notes on the employment of iodine in various pathological conditions The message which he wishes to place on record at the end of a long professional career is that iodine as a remedy in many conditions is not sufficiently recognised After reference to the successes obtained by the external use of iodine in adenitis, a method of treatment which is now largely superseded by other measures, he writes as follows:

> "I was called about three years ago to see a boy of 8 years who had three large strumous glands protruding from the right side of his neck by the angle of the jaw His mother said she had made an arrangement to have these glands enucleated on the following morning The temptation was irresistible I told her I should do what I could for the boy I gave them some ungt iodi denigrescens, and on the following day I found the glands reduced greatly in size and on the third day they had disappeared Two days after she called again to say the glands on the left side were growing I asked if she had used the ointment. She said she had not I asked if she had got any left She replied 'Plenty' 'Well,' I said, 'go home and use it' She called on me two days after to say the glands had quite gone"

Other successes with iodine that have stayed in his memory include the use of iodine ointment in a rheumatic shoulder and in a case of "housemaid's knee" Of the 1918 epidemic of influenza he writes —

> "A terrible epidemic of which I think I had more than my share of cases In each case on the first indication of pneumonia I had the patient's chest well rubbed with ungt iodi denigrescens fitted with a Gamgee jacket and given a cough mixture which contained, in each dose of an ounce 10 grains of iodide of potassium I prescribed a diet of milk and bovril, and, when necessary small doses of pure *malt* whiskey."

A wise little note is appended with regard to the purity of the spirit

Dr Burton was for 54 years Surgeon to the Birmingham district of the Great Western Provident Society, and is critical of the National Insurance Act which brought this side of his professional work to a close. He had many opportunities during that long period of observing the beneficial effects of iodine in superficial lesions He had 600 men to deal with and all varieties of injury, especially among carmen whose ulcerations were caused by the handling of packages of all sorts, sometimes containing such dangerous material as hides Under his treatment he cannot remember that any abscess ever occurred; he ventures the question whether the external use of iodine might not be of service in the vesicular stage of small pox, being here reminiscent of the horrors of an epidemic of this disease which occurred in 1872, when he was the single-handed superintendent of an institution with 150 beds

His last note is a strictly personal one. Referring back to the substitution of iodine in cervical adenitis for surgical measures, he writes that no man has better reason than himself to award the highest praise to the skilful surgeon inasmuch as he owes his life to a successful operation performed upon him in his eighty-third year by Sir Gilbert Barling With Sir Gilbert Barling's permission he treated the superficial suppuration which attended the wound with iodine ointment, and this proved a great success

NEW PREPARATIONS

The Monsol preparations are the result of an industrial process invented by the late Dr. Ludwig Mond, and investigations have shown that while they contain the germicidal properties of phenol they are free from toxic or irritating effects The preparations are presented to the profession in four forms a liquid for external inflammatory conditions, an ointment for use in antiseptic dressings, capsules for alimentary disorders, and pastilles, designed for slow solution in the mouth, and directed to conditions in the pharynx or larynx The liquid can be diluted according to whether it is required for irrigations, sprays, dressings, packings, or tampons, while a solution of 1 in 20 Monsol can be used for cleaning instruments As a general strength 1 in 200 is suggested The ointment has been found useful in conditions where a bland protective dressing is desirable, and here the antiseptic and germicidal properties will have value to the dermatologist The capsules contain a germicidal equivalent of 120 minims of pure phenol, are tasteless, and are recommended in many toxic conditions of the bowel The Monsol preparations may be obtained from the Mond Staffordshire Refining Co, Ltd, 147, Victoria-street, London, S W 1

(1) Tricalcine, (2) Peptalmine —From the Scienta Products Laboratory in Paris we have received specimens of various cachets of Tricalcine, a drug designed for use in conditions where the mineral elements of the body are deficient The importance to the economy of salts of lime does not need insisting upon, but tricalcine can only be of service if calcium, contained in assimilable form, is administered in connexion with strict dietetic treatment—acid foods must be vetoed, the amount of fat and bread taken reduced, and there should be a strict limitation of alcohol The cachets are supplied pure or "adrenalinated" (containing 3 drops of 1 1000 adrenalin solution in each cachet) or "methylarsinated" (containing 1 centigramme of pure methylarsinate of sodium in each cachet) or "fluorated" (containing 2 centigrammes of fluoride of calcium in each cachet), and the suggested dose in each case is 1 cachet three times a day just before food It should be added that the use of tricalcine in dental practice is a feature of the manufacturers' claims

From the same laboratory we have received two specimens of a drug termed Peptalmine for which it is particularly claimed that it will be of value in the forms of migraine of anaphylactic origin which have been made the especial subject of investigation by Widal, Richet and others It is supplied in granules or sugar-coated capsules and contains the peptones of meat and fish, with extracts of eggs and milk These two preparations may be obtained from Wilcox, Jozeau, and Co, 15, Gt St Andrew-street, W C 2

MIDWIFERY IN HONG-KONG.

The clinical report of the School of Midwifery and Gynæcology of the University of Hong-Kong for the year ending April, 1926, is a record of successful pioneer work, carried out under the usual difficulties, in raising the standard of efficiency of midwives and lying-in hospitals The work of the University clinic is greatly hampered by lack of space and shortage of nurses 463 patients were delivered in the 12 months, there were 5 deaths, 5 miscarriages, and 36 "morbid" cases Unfortunately, it is very hard to persuade Chinese mothers to remain in hospital more than three or four days Induction of labour was performed twice, once on an insane woman and once in order to persuade a patient whose urine was nearly solid with albumin to remain in hospital Full statistics are given in the report which was published in the *Caduceus* for November last Discussing the difficulty of getting nursing help, Prof R E Tottenham expresses the opinion that it would be worth while sending a few Chinese girls to a big teaching hospital in Europe so that they could form the nucleus of a Chinese staff

THE AMBULANCE TRAINS OF 1914.

A pamphlet written shortly after the war by Colonel G A Moore, Deputy Chief Commissioner St John Ambulance Brigade, has been reissued [1] It deals with the early days of our ambulance trains in France, was first published by Colonel Moore under the pseudonym of "Wagonlit," and was dedicated to the whole personnel who made and manned the ambulance trains in which tens of thousands of our sick and wounded were transported to the base in such comfort as could be devised in the opening weeks of the struggle When the first six detachments of ambulance men found themselves marching over the cobbled pavements of Boulogne a little more than a week after the declaration of war, there was not a single motor ambulance fitted railway coach available in the whole of France This contingency fortunately, the British War Office had foreseen and to some extent provided against by ingenious apparatus and make shifts Colonel Moore describes how the pioneers of t British Ambulance Train Service, 300 in number, began the work which was to have such splendid results, and so lustily did they struggle that in three weeks from arrival in France three ambulance trains had steamed to the front while a fourth was in hand From that point the experiences of the Ambulance Service, under the fluctuating and mostly ill-fortunes of the early days of the war, are clearly set down, among these being the dramatic occasion when, in the third week of September, the strain on all services was overpowering, and the personnel of the Service was hopelessly short, four sergeants and four privates, all qualified doctors, as well as certain medical students, with the regimental surgeon stepped out of the ranks of the London Scottish where they had enlisted This is a stirring record of the work done by doctors, students, and nursing sisters on those early ambulance trains, and Colonel Moore admits that his words "do not really describe their untiring energy, skill, and devotion to the 67,000 of England's best who travelled to sea bases in France between August, 1914, and April, 1915, on the 'First Twelve Ambulance Trains'"

THE RED CROSS IN JAPAN

The second Oriental Red Cross Conference recently held at Tokyo was attended by ministers and members of the *Japanese Royal Family* The Red Cross is well supported in Japan, for two and a half of the 80 million inhabitants belong to it, there are a million members of the Junior Red Cross, and the annual revenue exceeds £800,000 The meetings were held under the joint presidency of Baron Hiroshima, President of the Japanese Red Cross, and of Judge Payne, chairman of the League of Red Cross Societies which organised the conference Discussion centred round the questions how by popular appeal more thoroughly to prevent disease, such as tuberculosis, how to advance child welfare, how to combat venereal diseases and the abuse of opium, and how to diminish other infectious diseases. Red Cross nurses, of whom a number have been trained at the international courses organised by the League at Bedford College, London are highly esteemed in Japan, and are always selected for service when illness arises in the Royal Family An impressive exhibit was that of the Imperial Institute for Research on Nutrition, housed in one wing of the new Red Cross building, in its well-arranged museum are shown wax models of foods, fresh, stale or tainted, suitable meals for different groups—e g, working men or nursing mothers, the cost of each meal being always indicated These, as well as models of kitchens, sanitary plumbing, and other public health exhibits, are intended to be taken round for demonstration in the provinces Disaster relief for great calamities had its origin in Japan in 1888, when the Empress called on the Japanese Red Cross to help on the occasion of the volcanic eruption of Mount Bandai To what extent this form of activity is being developed may be seen in the March issue of the *World's Health*, the monthly publication of the League of Red Cross Societies

A NEW YORK CLINIC FOR CANCER

A campaign is said to have been started by the New York Cancer Association to collect £1,000,000 to establish an institution for treatment and study of cancer At a cost of £700,000 the Association has acquired a twenty-seven storey building called Hudson Towers, which is to be the cancer centre, with a hospital of 400 beds, a clinic capable of caring for 500 patients a day, laboratories for research, and a department devoted to public education in the prevention of cancer Hudson Towers was originally designed for a hospital and has been standing unfinished for some time Most of the 400 beds will be free, or available at a nominal charge It is estimated that there are something like 25,000 cases of cancer in the greater New York area

The Sandoz Chemical Works, Pharmaceutical Department, have opened new offices at 5, Wigmore street, W 1, for the convenience of the medical profession in London

Pasteurisation of Milk —The Health Committee of Blackpool has adopted a recommendation that all milk going into the town, apart from Certified Milk in sealed bottles, shall be pasteurised For this purpose it should pass through a clearing house, where it should be placed in sealed bottles and then sold to consumers The medical officer was requested to prepare a report on the medical aspect of the question

Lister Centenary Addresses.*

LISTER'S CONTRIBUTIONS TO PHYSIOLOGY.

By Sir CHARLES SHERRINGTON, O.M., F.R.C.P.,
WAYNFLETE PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF OXFORD; SOMETIME PRESIDENT OF THE ROYAL SOCIETY

THE invitation has been extended to me to offer a few words on the contributions made by Lister to physiology. Lister's very earliest scientific papers were all physiological Indeed he may be said to have entered by way of physiology his surgical researches which were to achieve so much

His first paper was on the Contractile Tissue of the Iris. Work done with the microscope which he used for the study of function rather than of form alone it appeared in 1853 in the first number of the first volume of the now well-known *Quarterly Journal of Microscopical Science* Lister was then 25 years of age. and that his maiden voyage of discovery should employ the microscope was but natural in the son of his father. Joseph Jackson Lister that remarkable man who leaving school at the age of 14 for the business he conducted so successfully yet found time to cultivate optics to such purpose as to be the main giver to the world of the achromatic microscope. Lister's earliest paper. this on the iris supplied the first full and correct description of the radiating muscle dilating the pupil It thus made a lasting mark upon its subject

Lister's second paper of a few months later, dealt likewise with involuntary muscle this time in the skin. where Koelliker had recently discovered the arrector muscles of the hairs: and this discovery Lister confirmed and in several respects extended.

ENTHUSIASM AND RESTRAINT.

We may be struck by the remoteness of these Lister's first themes both from surgery and from actual practice—they are simply academic I think we have to picture him a young man to whom what really mattered was engagement in research caring less what in particular the research might be, a young man so ardently curious about nature especially animate, nature that he turned enthusiastically to the problem that came first to hand And these papers in the simplicity of their text seem to reflect the Quaker upbringing of Lister's home There is already that sobriety of expression which characteristic of Lister all his life made yet the more impressive his own self-restrained statements of his great results later on. No man in his career had more excuse for. more justification for. hyperbole of phrase than had Lister. and no man ever indulged in hyperbole less than did he. It is therefore of significance when the young author allows himself an expansive adjective. as when he writes the grand discovery of plain muscle-cells' "the beautiful muscle of the iris" We feel these expressions to be from him not mere phrases An abiding interest of these youthful papers is their revelation of attributes in Lister's. so to say, original nature · and salient among these attributes are penetrative and faithful observation. catholic enthusiasm for research a restless testing of authority by observed fact. and unhesitating self-submission of opinion to whatever the truth might assert.

His third paper, still physiological and on the same theme smooth muscle followed some four years later. The cellular nature of that tissue had been denied · Lister returned to its further proof. and furnished it overwhelmingly Forty years afterwards the then foremost authority on this tissue wrote of this paper of Lister's as being still not only abreast but in several respects ahead of other subsequent papers on its subject

This work proved. however. to be Lister's farewell contribution to that particular theme. To him by then much had happened and was happening to compel his main interest elsewhere His scientific enthusiasm had indeed definitely orientated itself toward a chosen quest in the great field of the unknown His spirit of inquiry had found a direction of compelling interest to it . a lode-star of overpowering attraction In his own words written to his father he had fallen in love with surgery. And with that widely detailed and highly technical art and calling prospectively spread before him. the genius within him impelled him to study not so much this or that particular skill or difficulty. but the fundamental and all-pervading process of inflammation itself as being the prime and central problem for investigation as a surgeon

INFLAMMATION AND RELATED STUDIES.

Henceforward his physiological researches were merely side offshoots from that pathological study engaging his main thought Thus his paper on the nervous control or arteries distinguishing between the immediately local and the more distant effects of a stimulus and especially of an irritant stimulus upon the blood-vessels The local effect. he concluded. was independent of the nervous system. but with a surrounding zone of effect mediated by nerve a finding closely suggestive of present-day views Another paper was that on the pigment cells of the frog's skin the cells on which the animal's well-known colour changes depend Lister concluded the shift of pigment to be an active shift of the pigment grains within the cells themselves. and the way in which he consolidated and marshalled his evidence for that is a striking instance of his thoroughness as an investigator. There is little doubt that from detailed study of these pigment cells Lister gained much of that vivid and intimate conception of cell-life struggling against irritant agents which informed and directed his surgical strategy afterwards

Another physiological investigation by him concerned the inhibitory nature of certain visceral nerves He wrote ' I have been led to make an experimental inquiry into this so-called inhibitory agency' because it appears to me to have an intimate bearing upon the question how inflammation is developed through the medium of the nervous system at a distance from an irritated part His main conclusion was that inhibition resulted from more energetic action of those same nerves which when working mildly produce increased action Then and still more closely related to his pathological inquiries followed two papers on clotting of blood confirmatory as he himself remarks, of his conclusions arrived at about inflammation

THE MERIT OF LISTER'S EARLY RESEARCH

These papers and the year 1862 conclude practically the tale of Lister's researches devoted directly to physiology Of them the greater share were offshoots from his study of inflammation. They all possess the interest of revealing to us the features of their author in his earliest research career. Conspicuous in them is capacity for noting detail and the rarer power of sifting out from it the broader meanings Another of their qualities is a voracious appetite for observing for himself phenomena which many would be content to take on trust from the excellent descriptions already given by others Lister was satisfied by nothing less than seeing for himself and his eye never staled A further quality is their scientific courage which feared nothing except to miss the truth Moreover. even at this stage. though he might appear engaged on diverse problems. he was in fact centred upon one of which from his point of view the several were but several aspects Thus these early papers show that in reality quite early in his career he had not only found but had whole-heartedly flung himself upon what was to be his life-work and his life's problem—a problem we may almost subsume under the one broad term ' inflammation " That was the study which he was to follow to a practical solution so magnificently, and in doing so exhibit what these earlier paper had less opportunity for showing, the splendid power of establishing and systematically following to its consequences a great generalisation Hence from these earlier researches we can see spring that triumphant career of experimentation and observation, in the laboratory and the ward, which, with a really surprising speed of mastery, winged Surgery for that which she is to-day, a far-flighted angel of healing the civilised world over

---

* A series of three discourses delivered in the Robert Barnes Hall of the Royal Society of Medicine on April 6th.

ENLARGED SCOPE OF PHYSIOLOGY

But these papers, valuable though they are, whose features we have been examining, far from exhaust the gift made by Lister to physiology In addition to and beyond them he enriched it with the contribution of enhanced means towards its most cherished aims He put into the hands of physiology for all time to come a superlative refinement of its method and made possible observations otherwise impossible Sir Berkeley Moynihan has eloquently insisted on the importance of surgery as a means to discovery In physiology, how could Pavlov have achieved his epoch-opening study of the digestive processes except by leaning upon Lister's surgical principles ? Or Ferrier initiated his study of localisation of cerebral function except by means of Lister's surgical principles ? How could the physiologists of Toronto less than four years ago have bestowed upon diabetic sufferers that merciful remedy insulin, had it not been for the legacy of operative principle and science bequeathed to them and to the whole world by Lister ?

And Lister's own words leave us in no doubt as to what a source of rejoicing it was to him that among benefits accruing from his work was this of an enlarged scope and power for physiology and experimental medicine He dwelt, both in public and in priva upon the need and importance of such experimentati for the progress of knowledge necessary to civilisati He rejoiced that he had contributed to its pow And, indeed, the experimentalist owes to Lister instrument of research whose beneficent future t boldest imagination may well halt to set limit to

And of the gifts to Lister to humanity one whi the experimentalist is ever mindful of with espec gratitude is that, while helping man to mastery ov disease alike for animal and man, he contributed t free that necessary experimentation from the inflictio of pain Man, sacrificing animal life as he does t satisfy the material needs of human kind, has the rig to regard the intellectual need impelling him t animal experimentation as means of saving huma and animal-kind from disease, as being justified i doing so He feels the more jusified in doing so, an takes that step with a clear conscience, becaus largely owing to Lister it can be taken withou inflicting pain or suppuration

Thus it is that through years to come, after, indeed it may be that the actual papers contributed t physiology by him may have become matter chiefl for the historian and the antiquarian, Lister will still receive unfailingly his meed of commemoration from the physiologist and experimentalist, and in a manner which to himself would of all ritual and offering have been the most congenial—namely, in their daily observance and trust of methods which he discovered and inculcated, and in their practice for the alleviation and prevention of disease It is therefore with peculiar gratitude that physiology brings its tribute of admiration and veneration to the memory of one great even among the greatest of the benefactors of humanity, Joseph Lister

---

LORD LISTER AS A PATHOLOGIST AND BACTERIOLOGIST

BY WILLIAM BULLOCH, M D , F R S ,

GOLDSMITHS' COMPANY'S PROFESSOR OF BACTERIOLOGY,
UNIVERSITY OF LONDON

WE are met to commemorate the centenary of the birth of Lord Lister, and I have been asked to address this representative gathering on his contributions to pathological science Proud as I am of the great honour which has been bestowed on me, I am painfully conscious of my own imperfections and limitations for such a task My qualifications are twofold In the first place, I have read all Lord Lister's writings and have made a critical study of some of them, not only to discover their intrinsic merits, but to compare them with similar studies of his predecessors and contemporaries In the second place, I had the great privilege of knowing Lord Lister for 13 years, and in a manner which, considering the great disparity of our positions was, if I may presume to say so, almost intimate

As bacteriologist to the British Institute of Preventive Medicine I had to visit Lord Lister, the chairman of the Institute, almost weekly in order to report to him the progress of the work in the antitoxin department After I left the Institute, he frequently asked me to call upon him to discuss various scientific problems in which he was interested In this way I was a good deal in his company, and among the younger men of that day I probably saw as much of him as any one else When I first knew him, in 1895, he was 68, and I frequently saw him down to 1907 I last saw this great man in a bath-chair by the roadside at Walmer on a lovely sunny morning—Dec 26th, 1909 He was then 82, and was approaching the lonely end of his splendid career Both then and now he stands out to me as a most impressive personality I have known very many of the leaders in our profession at home and abroad during the last 30 years, and have no hesitation in placing him *facile princeps medicorum*

Up till old age he continued to be deeply interested in all medical advances and was almost young and boyish in his enthusiasm Although leading a busy and strenuous life he was still striving to keep abreast of bacteriological literature which at the time was pouring forth in an unbroken stream On several occasions I was hours in his company trying to unravel the intricate papers of Ehrlich and Bordet on the nature of hæmolysis or the constitution of diphtheria toxin Our hour of work finished he would relax into reminiscences of his life and aims, the difficulties he had to contend with, and how he had overcome them On one such occasion—the date was Oct 23rd, 1905—he referred in great detail to his work on pigmentation of the frog and on inflammation, and he said to me—I wrote the words down at the time—" if my works are read when I am gone, these will be the ones most highly thought of " These were not the numblings of senility, for he was still alert and fresh, but I took it to mean that he wished to be regarded as a scientist rather than as a surgical craftsman notwithstanding his pre-eminence in the latter branch of human activity It is therefore a peculiar pleasure to me to have to refer to some of these contributions which he himself valued

In estimating Lord Lister's scientific work it is essential to remember that he had no properly equipped laboratory as we understand it to-day His laboratory was his study in his private home, and perhaps the best part of his scientific work was that done in 11, Rutland-street, Edinburgh, during his first stay (1853–1860) in the Northern capital To this period belong the papers on pigmentation of the frog (1857), the function of the visceral nerves (1858), the coagulation of the blood (1858–1863), and the early stages of inflammation (1857) The construction of his antiseptic system took place mainly in the Glasgow period, 1860–1869, while his chief bacteriological studies are to be referred to the second stay in Edinburgh (1869–1877) when he resided at 9, Charlotte-square

The hours for his scientific work were early in the morning and far into the night, following a harassing day of active surgery in private or in hospital. He undertook his experimental work so that he might speak with first-hand knowledge of the themes he had to teach. Many of the problems, although of paramount importance practically, were obscure and complicated. Some were not capable of solution then, others have not yet been definitively resolved.

COAGULATION OF THE BLOOD

The coagulation of the blood has at all times excited wonderment, and the theories to explain the process have been innumerable and are still being brought forth. In this country very notable advances were made in the eighteenth century by William Hewson, who unfortunately died before he was 35. He proved that the red blood corpuscles were biconcave discs; he discovered the white corpuscles and performed a large number of admirable experiments to explain the process of clotting, although he never quite cleared up the mystery of its nature. His successors in the nineteenth century were not more happy. Coagulation was early studied by Lister as it was constantly being brought to his notice in connexion with closure of the vessels, putrefaction, and secondary hæmorrhage in surgical wounds. When Lister began, the prevailing theory was that of B. W. Richardson, who referred coagulation to the escape of ammonia which was believed in some way to hold the coagulative elements normally in solution. In a long series of experiments conceived and carried out in masterly fashion, Lister showed that the ammonia theory was untenable. He clearly saw the necessity for separating the nature from the cause of coagulation, and while baffled with the former he revealed by his experiments that the latter—the cause of coagulation—is really due to the influence exerted on the blood by the contact, even momentarily, of ordinary matter of some kind. He considered that this contact brings about a reaction between the solid and fluid constituents of the blood so that the corpuscles imparted to the liquor sanguinis the disposition to clot. As regards the cause of clotting it cannot be said that we have materially advanced during the 70 years since the publication of Lister's work.

EARLY STAGES OF INFLAMMATION.

Another basic pathological process which he studied was inflammation. The extraordinary changes which we call inflammation have always attracted attention, and the explanations given constitute a large part of the history of medical doctrines. When Lister began to study inflammation there was already a considerable mass of accurate knowledge on the subject. The older pathological anatomy so ably created by Morgagni and followed up by the French school down to the time of Cruveilhier, was being replaced by the new knowledge which accrued from the discoveries of Schleiden and Schwann. At the time Edinburgh was a great centre of medical activity and a nursery of medical talent. Many of her graduates migrated across the border to attain fame in the arenas of the South. I need only mention names like Richard Bright, Hodgkin, Thomas Addison, C. J. B. Williams, Marshall Hall, and two who had a marked influence on Lister's life at University College and afterwards, I refer to William Sharpey, and the exceedingly able, if eccentric, Wharton Jones. Their work was carried forward by Augustus V. Waller and the little known but highly successful worker William Addison. In the inflammatory process the margination of the leucocytes was taught by C. J. B. Williams and W. Addison in 1841. In 1846 Volney Waller rediscovered the wonderful process of emigration of leucocytes, previously known to Dutrochet (1827). In a most scholarly manner Wharton Jones summed up all the knowledge on inflammation down to 1846, and himself gained the Astley Cooper Prize in 1850 for his splendid essay on the pathology of inflammation.

When, therefore, Lister began to study the process he was traversing ground already trodden. He early realised, however, that much that had been done concerned the later stages of inflammation, whereas its real essence was most likely to be found by analysing the earliest changes. Examining the frog's web and the bat's wing he took elaborate precautions that they should be in a perfectly healthy condition. By the application of irritants he passed to the study of the morbid, and investigated especially the aggregation of the red corpuscles, their increased adhesiveness, and the structure of the arterioles and capillaries. He found that the capillaries alter in size, but referred the change to something inherent in their elasticity. While admitting the existence of contractility in the capillaries, modern writers have not accepted his explanation. Lister regarded irritants as acting in a twofold manner. The primary effect was a dilatation of the vessels, brought about through the influence of the nervous system and not limited to the *locus* of the irritant. The secondary effect, on the other hand, was the direct outcome of the irritamentum itself in consequence of which the blood becomes altered physically. The red discs become more adhesive, they accumulate in masses, and may bring about a condition of actual stasis. Strange to say, Lister made no reference to diapedesis of the leucocytes and probably missed it altogether. The earlier discovery of Waller had left apparently little impress on the knowledge of the day, so that when Cohnheim described diapedesis in detail in 1867 the discovery was looked upon as something altogether new. It is to Lister's credit that he discussed inflammation from a new point of view, which Cohnheim nine years later carried to a conclusion.

BACTERIOLOGY.

When Lister embarked on his extended study on the cause of suppuration and the complications which follow surgical operations, his previous work on blood and inflammation was a great help to him. He was continually groping for the causes of the surgical disasters which were habitually happening, but light began to peer through the obscurity. This was early during his Glasgow term. In 1865 his attention was directed by a colleague to the work which had been done on fermentation and putrefaction by Pasteur from 1857 onwards. This work came upon him as a revelation, and almost at once he grasped the full significance of the Frenchman's discoveries for surgery. Ten years later he tells us specifically that the work of Pasteur "long since made me a convert to the germ theory, and it was on the basis of that theory that I founded the antiseptic treatment of wounds in surgery."

Although he frequently reiterated his indebtedness to Pasteur it is, I think, a vulgar error to regard Lister as a mere imitator of his great French contemporary. As early as 1861, and before his acquaintance with Pasteur's papers, he was getting near the truth about suppuration, and afterwards he advanced beyond the point where Pasteur had led him. From now on he became ardent in the pursuit of bacteriology. This was about 1870, when the study of microbes had scarcely emerged as a distinct science. At the time there were two conflicting views. The one, supported particularly by the eminent botanist Ferdinand Cohn, held that bacteria exhibited a constancy in form which might be used as a basis of their classification into genera and species. According to the other view, there is no such morphological stability, but rather a pleomorphism whereby one and the same microbe could assume different forms according to the environment. In his earliest bacteriological work in 1873 Lister ranged himself among the pleomorphists, and it has to be admitted that he suffered shipwreck when he stated that Ehrenberg's and Cohn's classification was "entirely untrustworthy." Lister's mistake was one made by a great many others at that time, and serves but to show how unwary the earlier bacteriologists were of the pitfalls lying in their path. There exists an exceedingly interesting correspondence which passed between Lister and Pasteur on the subject. Pasteur clearly saw where Lister had erred and advised him to a practical solution so magnificently, and in doing so exhibit what these earlier paper had less opportunity for showing, the splendid power of establishing and systematically following to its consequences a great generalisation Hence from these earlier researches we can see spring that triumphant career of experimentation and observation, in the laboratory and the ward which, with a really surprising speed of mastery, winged Surgery for that which she is to-day, a far-flighted angel of healing the civilised world over

ENLARGED SCOPE OF PHYSIOLOGY

But these papers, valuable though they are, whose features we have been examining, far from exhaust the gift made by Lister to physiology In addition to and beyond them he enriched it with the contribution of enhanced means towards its most cherished aims He put into the hands of physiology for all time to come a superlative refinement of its method and made possible observations otherwise impossible Sir Berkeley Moynihan has eloquently insisted on the importance of surgery as a means to discovery In physiology, how could Pavlov have achieved his epoch-opening study of the digestive processes except by leaning upon Lister's surgical principles ? Or Ferrier initiated his study of localisation of cerebral function except by means of Lister's surgical principles ? How could the physiologists of Toronto less than four years ago have bestowed upon diabetic sufferers that merciful remedy insulin, had it not been for the legacy of operative principle and science bequeathed to them and to the whole world by Lister ?

And Lister's own words leave us in no doubt as to what a source of rejoicing it was to him that among benefits accruing from his work was this of an enlarged scope and power for physiology and experimental medicine He dwelt, both in public and in private, upon the need and importance of such experimentation for the progress of knowledge necessary to civilisation He rejoiced that he had contributed to its power And, indeed, the experimentalist owes to Lister an instrument of research whose beneficent future the boldest imagination may well halt to set limit to

And of the gifts to Lister to humanity one which the experimentalist is ever mindful of with especial gratitude is that, while helping man to mastery over disease alike for animal and man, he contributed to free that necessary experimentation from the infliction of pain. Man, sacrificing animal life as he does to satisfy the material needs of human kind, has the right to regard the intellectual need impelling him to animal experimentation as means of saving human and animal-kind from disease, as being justified in doing so He feels the more jusified in doing so, and takes that step with a clear conscience, because largely owing to Lister it can be taken without inflicting pain or suppuration

Thus it is that through years to come, after, indeed, it may be that the actual papers contributed to physiology by him may have become matter chiefly for the historian and the antiquarian, Lister will still receive unfailingly his meed of commemoration from the physiologist and experimentalist, and in a manner which to himself would of all ritual and offering have been the most congenial—namely, in their daily observance and trust of methods which he discovered and inculcated, and in their practice for the alleviation and prevention of disease It is therefore with peculiar gratitude that physiology brings its tribute of admiration and veneration to the memory of one great even among the greatest of the benefactors of humanity, Joseph Lister

---

LORD LISTER AS A PATHOLOGIST AND BACTERIOLOGIST

BY WILLIAM BULLOCH, M D , F R S ,
GOLDSMITHS' COMPANY'S PROFESSOR OF BACTERIOLOGY,
UNIVERSITY OF LONDON

WE are met to commemorate the centenary of the birth of Lord Lister, and I have been asked to address this representative gathering on his contributions to pathological science Proud as I am of the great honour which has been bestowed on me, I am painfully conscious of my own imperfections and limitations for such a task My qualifications are twofold In the first place I have read all Lord Lister's writings and have made a critical study of some of them, not only to discover their intrinsic merits, but to compare them with similar studies of his predecessors and contemporaries In the second place, I had the great privilege of knowing Lord Lister for 13 years and in a manner which considering the great disparity of our positions was if I may presume to say so almost intimate

As bacteriologist to the British Institute of Preventive Medicine I had to visit Lord Lister the chairman of the Institute, almost weekly in order to report to him the progress of the work in the antitoxin department After I left the Institute he frequently asked me to call upon him to discuss various scientific problems in which he was interested In this way I was a good deal in his company, and among the younger men of that day I probably saw as much of him as any one else When I first knew him, in 1895, he was 68 and I frequently saw him down to 1907 I last saw this great man in a bath-chair by the roadside at Walmer on a lovely sunny morning—Dec 26th, 1909 He was then 82, and was approaching the lonely end of his splendid career Both then and now he stands out to me as a most impressive personality I have known very many of the leaders in our profession at home and abroad during the last 30 years, and have no hesitation in placing him *facile princeps medicorum*

Up till old age he continued to be deeply interested in all medical advances and was almost young and boyish in his enthusiasm Although leading a busy and strenuous life he was still striving to keep abreast of bacteriological literature which at the time was pouring forth in an unbroken stream On several occasions I was hours in his company trying to unravel the intricate papers of Ehrlich and Bordet on the nature of hæmolysis or the constitution of diphtheria toxin Our hour of work finished he would relax into reminiscences of his life and aims, the difficulties he had to contend with, and how he had overcome them On one such occasion—the date was Oct 23rd, 1905—he referred in great detail to his work on pigmentation of the frog and on inflammation, and he said to me—I wrote the words down at the time—" if my works are read when I am gone, these will be the ones most highly thought of " These were not the mumblings of senility, for he was still alert and fresh, but I took it to mean that he wished to be regarded as a scientist rather than as a surgical craftsman notwithstanding his pre-eminence in the latter branch of human activity It is therefore a peculiar pleasure to me to have to refer to some of these contributions which he himself valued

In estimating Lord Lister's scientific work it is essential to remember that he had no properly equipped laboratory as we understand it to-day His laboratory was his study in his private home, and perhaps the best part of his scientific work was that done in 11, Rutland-street, Edinburgh, during his first stay (1853–1860) in the Northern capital To this period belong the papers on pigmentation of the frog (1857) the function of the visceral nerves (1858), the coagulation of the blood (1858–1863), and the early stages of inflammation (1857) The construction of his antiseptic system took place mainly in the Glasgow period, 1860–1869 while his chief bacteriological studies are to be referred to the second stay in Edinburgh (1869–1877) when he resided at 9, Charlotte-square

The hours for his scientific work were early in the morning and far into the night following a harassing day of active surgery in private or in hospital He undertook his experimental work so that he might speak with first-hand knowledge of the themes he had to teach Many of the problems, although of paramount importance practically, were obscure and complicated Some were not capable of solution then, others have not yet been definitively resolved

Coagulation of the Blood

The coagulation of the blood has at all times excited wonderment, and the theories to explain the process have been innumerable and are still being brought forth. In this country very notable advances were made in the eighteenth century by William Hewson, who unfortunately died before he was 35 He proved that the red blood corpuscles were biconcave discs, he discovered the white corpuscles and performed a large number of admirable experiments to explain the process of clotting, although he never quite cleared up the mystery of its nature His successors in the nineteenth century were not more happy Coagulation was early studied by Lister as it was constantly being brought to his notice in connexion with closure of the vessels, putrefaction, and secondary hæmorrhage in surgical wounds When Lister began, the prevailing theory was that of B W Richardson who referred coagulation to the escape of ammonia which was believed in some way to hold the coagulative elements normally in solution In a long series of experiments conceived and carried out in masterly fashion, Lister showed that the ammonia theory was untenable He clearly saw the necessity for separating the nature from the cause of coagulation, and while baffled with the former he revealed by his experiments that the latter—the cause of coagulation—is really due to the influence exerted on the blood by the contact, even momentarily, of ordinary matter of some kind He considered that this contact brings about a reaction between the solid and fluid constituents of the blood so that the corpuscles imparted to the liquor sanguinis the disposition to clot As regards the cause of clotting it cannot be said that we have materially advanced during the 70 years since the publication of Lister's work.

Early Stages of Inflammation

Another basic pathological process which he studied was inflammation The extraordinary changes which we call inflammation have always attracted attention, and the explanations given constitute a large part of the history of medical doctrines When Lister began to study inflammation there was already a considerable mass of accurate knowledge on the subject The older pathological anatomy so ably created by Morgagni and followed up by the French school down to the time of Cruveilhier, was being replaced by the new knowledge which accrued from the discoveries of Schleiden and Schwann At the time Edinburgh was a great centre of medical activity and a nursery of medical talent Many of her graduates migrated across the border to attain fame in the arenas of the South I need only mention names like Richard Bright, Hodgkin, Thomas Addison C J B. Williams, Marshall Hall, and two who had a marked influence on Lister s life at University College and afterwards, I refer to William Sharpey, and the exceedingly able if eccentric, Wharton Jones Their work was carried forward by Augustus V. Waller and the little known but highly successful worker William Addison In the inflammatory process the margination of the leucocytes was taught by C J B Williams and W Addison in 1841 In 1846 Volney Waller rediscovered the wonderful process of emigration of leucocytes, previously known to Dutrochet (1827) In a most scholarly manner Wharton Jones summed up all the knowledge on inflammation down to 1846 and himself gained the Astley Cooper Prize in 1850 for his splendid essay on the pathology of inflammation.

When, therefore, Lister began to study the process he was traversing ground already trodden He early realised, however, that much that had been done concerned the later stages of inflammation, whereas its real essence was most likely to be found by analysing the earliest changes Examining the frog's web and the bat s wing he took elaborate precautions that they should be in a perfectly healthy condition By the application of irritants he passed to the study of the morbid, and investigated especially the aggregation of the red corpuscles, their increased adhesiveness, and the structure of the arterioles and capillaries. He found that the capillaries alter in size, but referred the change to something inherent in their elasticity. While admitting the existence of contractility in the capillaries, modern writers have not accepted his explanation Lister regarded irritants as acting in a twofold manner The primary effect was a dilatation of the vessels brought about through the influence of the nervous system and not limited to the *locus* of the irritant The secondary effect, on the other hand, was the direct outcome of the irritamentum itself in consequence of which the blood becomes altered physically The red discs become more adhesive, they accumulate in masses, and may bring about a condition of actual stasis Strange to say, Lister made no reference to diapedesis of the leucocytes and probably missed it altogether The earlier discovery of Waller had left apparently little impress on the knowledge of the day, so that when Cohnheim described diapedesis in detail in 1867 the discovery was looked upon as something altogether new It is to Lister's credit that he discussed inflammation from a new point of view, which Cohnheim nine years later carried to a conclusion

Bacteriology.

When Lister embarked on his extended study on the cause of suppuration and the complications which follow surgical operations his previous work on blood and inflammation was a great help to him. He was continually groping for the causes of the surgical disasters which were habitually happening, but light began to peer through the obscurity This was early during his Glasgow term In 1865 his attention was directed by a colleague to the work which had been done on fermentation and putrefaction by Pasteur from 1857 onwards This work came upon him as a revelation, and almost at once he grasped the full significance of the Frenchman's discoveries for surgery Ten years later he tells us specifically that the work of Pasteur "long since made me a convert to the germ theory, and it was on the basis of that theory that I founded the antiseptic treatment of wounds in surgery"

Although he frequently reiterated his indebtedness to Pasteur it is I think, a vulgar error to regard Lister as a mere imitator of his great French contemporary As early as 1861, and before his acquaintance with Pasteur's papers, he was getting near the truth about suppuration, and afterwards he advanced beyond the point where Pasteur had led him From now on he became ardent in the pursuit of bacteriology This was about 1870, when the study of microbes had scarcely emerged as a distinct science. At the time there were two conflicting views The one, supported particularly by the eminent botanist. Ferdinand Cohn, held that bacteria exhibited a constancy in form which might be used as a basis of their classification into genera and species According to the other view, there is no such morphological stability, but rather a pleomorphism whereby one and the same microbe could assume different forms according to the environment In his earliest bacteriological work in 1873 Lister ranged himself among the pleomorphists, and it has to be admitted that he suffered shipwreck when he stated that Ehrenberg's and Cohn's classification was "entirely untrustworthy" Lister's mistake was one made by a great many others at that time, and serves but to show how unwary the earlier bacteriologists were of the pitfalls lying in their path There exists an exceedingly interesting correspondence which passed between Lister and Pasteur on the subject Pasteur clearly saw where Lister had erred and advised him to repeat his experiments with added precautions. This Lister did and profiting by his new experience, became one of the foremost bacteriological technicians and pioneers of his time. So imbued was he with lofty ideals that instead of covering up his tracks he handsomely admitted his error. "Next to the promulgation of truth," he said, "the best thing I can conceive that a man can do is the recantation of a published error." This sentiment was almost exactly that which was given to us sixteen hundred years ago by Celsus who however, added that such a confession is suited only to a great genius whose splendour is such as to survive the sacrifice, especially in the performance of a task which is to be handed down for the benefit of posterity as a beacon of truth to warn them against similar errors. From the theory of Cohn and Pasteur it was to be presumed that in some way—at that time unknown—bacteria might be separated from each other and cultivated in a pure state. The great mycologist, Brefeld early pointed out the necessity of raising pure strains or cultures from one single germ. Lister attempted this and by unsurpassed technique involving a remarkable understanding of the whole problem he succeeded in obtaining a pure growth of a microbe which he called *Bacterium lactis*, and which was a cause of the so-called lactic fermentation. He grew the microbe in sterile milk and raised a pure strain, constant morphologically and physiologically, from a single bacterial cell. This was possible by the aid of an ingeniously constructed syringe of his own invention. He also introduced several of the methods of sterilisation which are in constant use to-day. His work on lactic fermentation is a classic and stands as a model of what a scientific research should be.

Like Pasteur Lister had the supreme faculty of seeing as if by instinct the exact experiment required to eliminate an element of doubt or to advance ahead. He was a master of the experimental method—a rare and precious gift which the Abbate Spallanzani truly said "has always been confined and always will be confined to the few."

Conclusion

And now I am at the end. No one could come into contact with Lister without being impressed by his noble personality, his magnanimity, his liberality, and his modesty. His aims were of the loftiest kind and probably *no medical man ever kept more* steadfastly before his gaze the covenants of the Hippocratic oath. He venerated his teachers, he taught his art to his pupils, he kept nothing secret from his profession and followed that system which, according to his ability and judgment he deemed best in the interest of his patients. With purity and holiness he passed his life and practised his art.

When one looks down the long vista of time and contemplates the art of medicine three names stand prominent, and we should all feel pride in our English stock which gave birth to Harvey to Jenner, and to the great Lister—a name to resound for ages.

LISTER AS SURGEON.

By Sir BERKELEY MOYNIHAN, Bart.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

Seldom is a great discovery the product of one man's mind. In the work of other men it has ancestors, forerunners possessing one or more attributes whose final and felicitous association within new work constitutes new truth. When that new truth is fully disclosed its relation to many other truths familiar *to all for perhaps many years and in many associations* becomes clear. The claim may then arise that those who have revealed isolated and antecedent truths have priority in the final discovery. Such truths are however only progenitors with no claim to be regarded as their own descendant, the new truth itself.

Pre-Listerian Surgery

The immortality of Lister whose centenary we commemorate to-day, is due to discoveries which did for the craft of surgery what John Hunter had done for its science. The oldest human remains bear evidence of surgery. Before Lister came operations had been relatively few, because of their heavy mortality and their almost insupportable burden of terror and of suffering. Every operation risked the life of the patient from one single cause putrefaction in the wound. So frequent was this that it was always expected, and whenever it appeared no man might foresee or measure its consequences. Evidence of this we find on almost every page of the old text-books and in the biographies of the great surgeons. It is startling to read that when in the year 1821 Astley Cooper operated upon George IV for a small sebaceous cyst on the head so tortured was he by anxiety lest erysipelas or pyæmia might develop that he sought to put upon others the responsibility of the operation, on Cline on Everard Home on anybody but himself. He speaks of the operation in terms which to us now appear absurd fearing that "it might by possibility be followed by fatal consequences." He says "I saw that the operation if it were followed by erysipelas would destroy all my happiness and blast my reputation," and "I felt giddy at the idea of my fate hanging upon such an event" and again, "I am certain that if anything happened to the King that at any rate, I should leave London and live in retirement." It is hard to believe that a surgeon eminent enough to be chosen for service to the King should be so deeply moved at the prospect of what was to him, as to us technically the simplest of operations. The exercise of the art of surgery brought terror then where it now brings joy, to surgeon no less than to patient.

Steps in the Discovery

Lister's discovery was very gradual. His earliest interests in surgical inquiry were concerned with *inflammation*, its cause, its *nature* and possible methods of controlling it. *In this as in many of his* earlier investigations Hunter was both inspiration and guide. His paper on "On the Flow of the Lacteal Fluid in the Mesentery of the Mouse" published in 1857, but based on researches begun in 1853, is an extension of Hunter's experiments on absorption. His studies on coagulation of the blood began with a investigation on the blood in the veins of sheep's "trotters" obtained from the slaughter-house. By devising neat and critical experiment he was able to carry knowledge of coagulation of the blood far beyond the point which Hunter and Hewson had *attained* a century before. Yet the methods he employed were clearly modifications of those used by his great forerunner. By such investigations as these Lister was training himself, but his chief interest lay always in the problem of the healing of wounds. When, therefore he learnt of Pasteur's researches his mind was open to the new truths and expectant of them. Before the British Medical Association in Dublin in 1867 he said:—

> "In the course of an extended investigation into the nature of inflammation, and *the healthy and* morbid conditions of the blood in relation to it, I arrived several years ago at the conclusion that the essential cause of suppuration in wounds is decomposition brought about by the atmosphere upon blood or serum retained within them, and, in the case of contused wounds, upon portions of tissue destroyed by the violence of the injury. To prevent the occurrence of suppuration with all its attendant risks was an object manifestly desirable, but, till lately apparently unattainable, since it seemed hopeless to exclude the oxygen which was universally regarded as the agent by which putrefaction was effected. But when it had been shown by the researches of Pasteur that the septic properties of the atmosphere depended not on oxygen or any *gaseous constituent*, but on minute organism suspended in it, which owed their energy to their vitality, it occurred to me that decomposition in the injured part might be avoided without excluding the air by

applying as a dressing some material capable of destroying the life of the floating particles"

Lister's first step was therefore a realisation of the truth that decomposition in wounds depends upon the activity of living micro-organisms, his second which followed immediately, was based upon the belief that such organisms might be destroyed in the wound, or as they were about to enter the wound, his third and last, which came more slowly was founded upon the hope that the organisms within the field of operation might be destroyed before they entered the wound.

Around every step of his advance fierce controversy raged. The scepticism and hostility of early contemporaries was stupid unimaginative and petty. The history of science is not only the story of new truths and their slow emergence from error, it is a recital of bitter and vexatious opposition from those who should have been the first to acclaim and to welcome the new vision. Only a few weeks ago we learnt once again of the diffidence of Isaac Newton in the publication of discoveries made years before, his reluctance was due in part, perhaps, to a native modesty and indifference to the applause of others; in part also to shrinking of a sensitive nature from the acrimony and coarseness of controversy.

The rank hostility of Riolan to Harvey, the disdainful incredulity of Liebig at the discoveries of Pasteur, are in direct intellectual relation to the revolt of Calvin at the discoveries of Servetus, the animosities of the Church which martyred Giordano Bruno, the threat of torture which subdued the aged Galileo, and all that long record of sinister events which proclaims the inveterate hostility of impervious minds to novelty. For such minds novelty is always error, truth is bent through an angle of refraction as it enters them. Lister's answer to indifference, opposition, and denial was unfaltering continuance in inquiry and experiment, and in the demonstration day by day, and case by case of changed results.

The Heavily Infected Wound

Few, if any, now living remember the full horror of the old days. But an experience not dissimilar awaited us in the earliest days of the Great War. A pestilence of infection to which we were wholly unaccustomed turned our faces towards the early struggles of Lister. On all sides we heard that our inability to check a raging suppuration in a heavily infected wound proclaimed the failure of Lister's methods. So to Lister we turned again, only to realise much more acutely how the problems which faced us had been his problems, how our experience, horrible in its new revelation had in the first years of his practice been his daily experience. Reading Lister's works with clearer perception and new understanding of the difficulties by which he was confronted, our admiration of his patience insight, and courage glowed into greater reverence than ever before. Lip service we had long given to the founder of the new era; we were now compelled to realise that Lister is indeed the man who has saved more lives than all the wars of all the ages have thrown away, the man who has changed the face of surgery, the one man who has in truth created if not a new art, at least a new and safe and illimitable opportunities for the practice of the old art.

The first conception in Lister's mind in respect of treatment was that the organisms within the wound, and those entering the wound, might be destroyed by some chemical agent the nature of which was to be determined by a series of experiments. From time to time changes were made as search brought to light some new chemical substance more active in destroying bacteria and less harmful to the living tissues of man. The search is not ended yet. Up to this moment it has engaged the interest of such men as Dakin, Browning, and J B Cohen, and no doubt it will long continue. The problem however is not merely that of accomplishing highest bacterial destruction with lowest cellular injury: it is rather one of augmenting the natural powers of cells and of serum to subdue and destroy bacteria and their poisons. Lister. I feel confident realised all this to a greater degree than many of his successors. Godlee in his life of Lister makes this quite clear. Though the earliest efforts were concerned with the abatement of existing decomposition of wound discharges, it was not long before the problem of the prevention of infection became paramount. It is beyond dispute that Lister clearly realised the distinction between the "prophylactic" and the "therapeutic" uses of chemical agents in surgery. We know now that the old quarrel as to the relative merits of the "antiseptic" and the 'aseptic" methods was senseless and jejune; for Lister was indubitably the parent of both, if, indeed there are really two methods. No surgeon ever practised with success a method in which agents for the destruction of organisms were omitted. Aseptic surgery is the wise practice of antiseptic surgery. There is a difference in detail, not in ideal, or in fundamental truth.

Pasteur and Lister

We have no need to discuss the relative merits and claims of Pasteur and Lister. It is true that without Pasteur there would have been no Lister at the time when Lister was. Pasteur set out to discover the truth as to spontaneous generation and by crucial and magisterial experiment settled that problem once for all. While at Lille, in the centre of a district of many distilleries the problem of fermentation engaged his mind, and the assertion of Liebig foremost among chemists of his day, that it was "a change in organic fluids and tissues set in motion by the access of oxygen" was shown to be incomplete. The genius of Lister lay in immediate realisation of the fact that the biological truths established by Pasteur might be applied to other circumstances. His mind was prepared for the new vision by his physiological training. I make no attempt to exalt Pasteur by saying that Lister's work was corollary to his, nor to belittle Pasteur by speaking of his ignorance of the full effect of his work. Let the world be thankful for both. We who are within the profession of medicine have once again to learn that progress depends not only upon our own efforts in the discharge of our daily task of healing but upon an association as intimate as can possibly be with every aspect of biology.

Results, Immediate and Remote

The consequences of Lister's work are many and far-reaching. The immediate result was of course the complete abolition of many of the dangers attaching to the most certain and most dreaded peril of all infection in the wound extending to other parts, causing severe and protracted suffering, even grave risks to life itself. But when the few operations then practised became safe, it was obvious that other operations might be attempted. The result was that procedures condemned as "murderous," the practice of which should, in the opinion of high authority, lay a man open to a charge of manslaughter were greatly increased in number as soon as it could truthfully be claimed that the risk of operation was definitely less than the risk of inaction. The most exemplary instances were found in the practice of abdominal surgery. Ovariotomy, condemned by highest authority as homicidal (the Governors of King's College Hospital in 1877 had forbidden the staff to undertake it) became so safe in expert hands that neither patients nor surgeon hesitated in the choice of operation.

In all new advances in surgery it is only the patient whose disease has reached a high development threatening disability, suffering, or death, who is submitted to operation; the cases with the greatest risk already attached to them are the first to undergo adventurous treatment. As the safety of surgery is shown in these, similar cases are treated but in an earlier stage, a stage in which the surgical risks are less, the convalescence quicker, the mortality lower. Ultimately a fatality occurs only in the exceptional case, from causes connected rather with the original disease than with the operation practised. In my days as a resident in hospital ovariotomy was regarded as an operation of utmost gravity, and was performed with much ceremony in private wards and with special nurses. McGill, who led me by the hand along the path of surgery, always had a Turkish bath in the afternoon of the preceding day, and operated at an unusually early hour in the morning. Some mammoth tumours were removed, tumours which at times greatly outweighed what was left of the patient; indeed, we removed patient from tumour rather than tumour from patient. From ovariotomy an advance was made to the treatment of other pelvic conditions. Fibroid tumours of the uterus were eventrated and a constricting band of metal applied to the cervical stump which was brought up into the wound. When for the first time I returned the pedicle to the abdomen after the operation of hysterectomy, our obstetric physician, Dr. Braithwaite, quailed with horror at such temerity. The conquest of other disease of the abdomen was soon inaugurated; the campaign owed almost everything to those who had practised what we now call gynæcology. Spencer Wells removed the enlarged spleen from a patient whose tumour he had believed to be uterine; and a condition of tuberculous ascites miscalled "ovarian cyst" improved so much after the release of the fluid that similar cases were quickly claimed for surgical treatment.

The whole abdomen soon became the province of the surgeon, whose activities also rapidly extended to the cranial and thoracic cavities, so that at the present day neither technical difficulty nor any danger in the trauma inflicted prevents the surgeon from dealing with almost any lesion, wherever it may lie, or whatever its nature. There is scarcely any organ which cannot be attacked; there is no inherent and inescapable risk in any technical procedures.

SURGERY AS AN AVENUE OF RESEARCH

An extension of safe operative measures within the cavities, especially within the abdomen, has resulted in a complete revision of our knowledge of the earlier structural changes in many organs attacked by disease, and of the clinical manifestations which those changes produce. Surgery has proved an implement of research; it is indeed the most powerful of all, though this fact is not yet fully realised, nor is adequate use yet made of it. In the mortuary period of pathological knowledge only the most advanced stages of disease, those stages which at last proved fatal, could as a rule be examined. The final symptoms of the terminal changes in structure were, not perhaps the only, but they were certainly the chief, interest of the clinician; little was known of the dependence of earlier symptoms upon tissue changes. Pathologists and physicians alike were incredulous as to the truth or significance of much of the new knowledge which the surgeon was daily accumulating as the result of his widening observations. Even to-day the physiologist and physician do not appreciate how much is to be learnt at the bedside or in the operation theatre.

As an implement of research surgery has been generously used by the physiologist in his experiments upon animals. Perhaps the most entrancing exploit of all was that inaugurated in this country by Ferrier and pursued by Macewen, Horsley, Sherrington, and others, by which the functions of the various parts of the nervous system have been elucidated. There is something of enthralling interest in the story of the localisation of function in the cerebral cortex, in the realisation that in the convolutions of the brain exist allotments each with its own highly specialised and exclusive function. The work of the surgeon upon the abdominal viscera, his discoveries concerning not only changes of structure in various disease, but also disorders of visceral reflexes, and symptoms associated with these, have been not less arduous, nor less interesting, and even more fruitful in the clinical study of diseases, and in the relief of human suffering.

The capacity of the surgeon to enlarge the area of his operation has been used with gratifying success in the treatment of accessible cancer. The lines of extension of this disease have been the subject of inquiry by pathological anatomists, who have studied afresh not only the lymphatic systems of the various organs affected, but also the exact lines along which the cancer cells may drift or grow. The work of Sampson Handley on the breast and of Ernest Miles on the rectum are worthy of special commendation. Since we know beyond dispute that cancer is primarily a local disease, we know also that every accessible cancer is curable if operation is practised in the early stages of disease. That is not the least of the debts we owe to Lister. It is his work that has permitted us so to plan our operations that not the growth alone but also all those parts, such as lymphatic glands into which the growth makes haste to extend, can all be removed in one mass, and that infection is now the least of our anxieties.

ACCOMPLISHMENT

We may almost claim that the full effect of Lister's work is now accomplished. We know that for all time operations of every kind may be practised without the grave risks that formerly were prohibitive. The art of surgery is far in advance of all the sciences upon which its future progress depends. Until they stand abreast, or even advance ahead, the progress of surgery will be slow. The great search for us all must now be for the methods of applying new discoveries in other sciences, physiology, biochemistry, pathology, physics, and the like to the study of disease.

Many lines close in the dial's centre. From all the vast periphery of our surgical world messages of gratitude and of homage converge upon Lister to-day. Lister made possible the new surgery, beyond all question the most beneficent art mankind has ever practised. So long as there are men to live and suffer, so long will Lister be there to heal them, to hold the gates of life ajar.

To the honoured dead we raise our monuments, some cast in bronze, some graven in stone; some like that of immortal Hunter, begun in a man's lifetime, the work of his own hands, are enlarged and lovingly enriched through generation after generation by those who labour in the master's cause. On the roll of honour which in letters of gold bears the names of the saviours of mankind no man is more worthy of remembrance than Lister. His living and enduring memorial is a great, and ever greater multitude of men, women, children of every nation of every race of every creed through his mercy, and by the skill of his most gentle hand relieved from infirmity and suffering and sorrow, and made for a time triumphant over death itself.

It is immortal Lister we salute to-day, the supreme benefactor of mankind.

LONDON CHILDREN'S HOSPITALS.—The Prince of Wales last week opened a new wing of the Belgrave Hospital for Children, Clapham-road, S.W., of which he is patron. This addition completes the hospital as originally designed, but it is hoped soon to provide a nurses' home and a larger out-patients' department. During the past four years £40,000 has been spent in the building and equipment of two new wings. The institution, which is situated near the Duchy of Cornwall estate, is the only hospital for sick children in South-West London south of the Thames.—At the annual Court of Governors of the East London Hospital for Children, Shadwell, it was stated that the year's deficit of £2000 was largely owing to the obscure position of the institution, "hidden away in the East-End, among high buildings, while bigger hospitals on the main roads have a daily advertisement."—It is hoped to open the Princess Louise Kensington Hospital for Children in September next, and the board of management are about to appoint the honorary medical staff. Upon opening there will be 15 beds; in the near future there will be 30, and eventually the number will be increased to 50. From the beginning there will be a large children's out-patient department, and a similar department for women.

Lumleian Lectures

ON THE

MUSCULAR MECHANISM OF RESPIRATION AND ITS DISORDERS.

The Second Lumleian Lecture delivered before the Royal College of Physicians of London on March 24th

BY SIR CHARLTON BRISCOE, BART,
M.D., F.R C P. LOND,
PHYSICIAN TO KING'S COLLEGE HOSPITAL AND TO
ST JOHN AND ST ELIZABETH HOSPITAL.

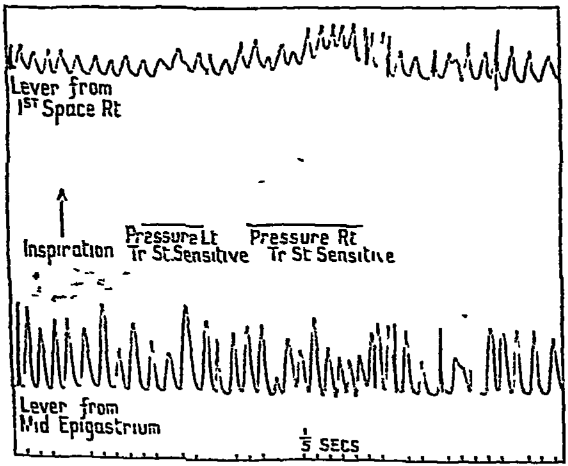
LECTURE II ‡

IN this lecture I propose to deal with certain stimuli which produce an alteration in normal physiological breathing This alteration mainly occurs in the level or "postural tone" of the different parts of the respiratory mechanism, and is shown by a diminution or by an increase of relaxation at the end of expiration The stimuli referred to may be transitory or persistent and of long standing, and may be considered to be of the nature of reflexes Where their action is intermittent the position adopted at the end of expiration will differ accordingly.

PAIN REFLEX

The first of these to be considered is the response to the sensation of pain experienced anywhere in the body The accompanying figure illustrates the result of pressure upon a tender muscle In this instance the triangularis sterni on the left side was sensitive, that on the right was still more sensitive The reaction from pressure on either of these muscles was similar, but more marked in the case of the right muscle than of the left When pressure was made with the little finger on the right muscle between the ensiform appendix and the costal margin there was a certain diminution of the movement of the epigastrium, and associated with it an increased movement and an elevation of the level of the thoracic tracing (Fig 1). This indicates therefore, that the relaxation in expiration, which would allow the thorax to resume its normal position, was inhibited—in other words, that a condition of persistent contraction or tone developed in one of the muscles which holds the thorax elevated. Digital examination of these muscles showed that this elevation was due to a persistent contraction or lack of relaxation in the anterior scalene muscle. This is but an illustration of the general experience of pain producing a prolonged gasp.

FIG. 1

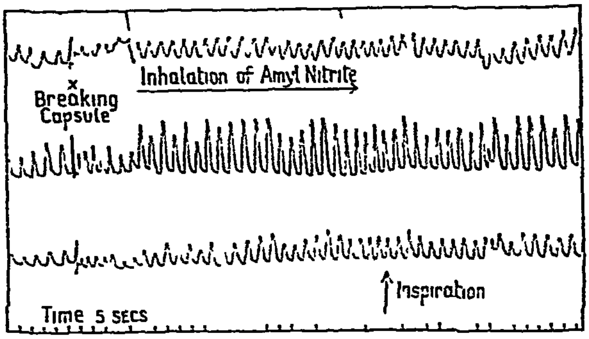


Pressure on a tender muscle produces an elevation of the level of the thoracic tracing

EMOTIONAL REFLEXES.

A similar alteration in mode of breathing occurs as the result of emotions During these observations one of the bugbears encountered was the diminution in the respiratory movement which almost invariably accompanied prolonged examination of an individual who remained in the same posture for a period of half an hour or more Sometimes this went further and the subject went to sleep * When this occurred it was constantly observed that the movement of the thorax was greatly diminished, or ceased, while that of the epigastrium was affected similarly, but to a less extent. Occasionally the individual waked up dreaming In the case of a boy of 16 who was the subject of investigation, a dream of a pleasurable nature occurred * He dreamed that he was at home in bed. This tracing shows an enhanced movement of the thorax which, at the same time, is accompanied by an elevation of the level of the tracing, again indicating that the *posture existing at the end of the expiratory phase* was higher than that during sleep, or before going to sleep

FIG. 2



Mental effect of administration of amyl nitrite The effect of hearing the capsule broken is to cause a rise in the level of the thoracic tracing The upper tracing refers to second left intercostal space, the middle tracing to the epigastrium, and the lower to the hypogastrium

This alteration occurs also very commonly as the result of unpleasant affects If, for instance, a medical student has agreed to submit himself to the inhalation of amyl nitrite, the same increased thoracic movement and elevation will occur when the glass capsule is broken (Fig 2) Or, if the investigation consists in the hypodermic injection of adrenalin, when the arm is held before inserting the needle, similar reactions are noted And again when there is suspicion as to the nature of the investigation elevation of the thorax is observed *

The group of cases termed "functional," in which may be included the anxiety neurosis, exhibit a prolonged emotional state characterised by a persistent reflex and results in an increased movement of the thorax foreign to the type of chest * Thoracic breathing is the habit of the functional case In these cases it is not possible to say positively that elevation has occurred, but it is a reasonable deduction from the maintenance of a continuous increased level, associated with an increased movement such as commonly occurs in the instances mentioned above It is, of course, impossible in such cases to obtain a tracing of the actual commencement of the condition It can, however, be observed that there is a persistent tone in the scalene muscles, and that the intercostal muscles of the upper spaces do not relax completely during expiration This is more noticeable on the left side than on the right

Darwin [19] showed that in some animals certain emotions caused an extension of the spine, and in my first lecture I showed that such extension of the spine is accompanied by an increased movement in inspiration of the thorax at the expense of the diaphragm Such, however, does not appear to be a full explanation, for in my observations given above there has been, so far as can be told, no alteration of the spine during the period of investigation The condition would be explained by a diminished relaxation of the scalene, an increased contraction of this muscle accompanied by increased stretch in the upper intercostal muscles †

---

‡ Lecture I. appeared on March 26th

* The asterisks throughout refer to points demonstrated by means of lantern slides

In my first lecture I showed a tracing of the effect of increasing the tension on the anterior scalene, which promoted an increased movement of the clavicle and upper ribs

Conscious Dyspnœa

It is a common experience that the conscious appreciation of shortness of breath is accompanied by an elevation of the chest, and this elevation must be produced by a similar mechanism Thus it appears that pain, emotion, transient or prolonged (as in functional cases), and conscious dyspnœa each tend to produce an alteration in the manner of breathing in the nature of a shift towards the thoracic type This is brought about by a diminished relaxation of certain muscles—e g , scalenes and upper intercostals—and leads to a raising of the expiratory level of the thorax The consequent stress on these muscles appears to me to be a factor of great importance in the pathology of the mechanism of respiration

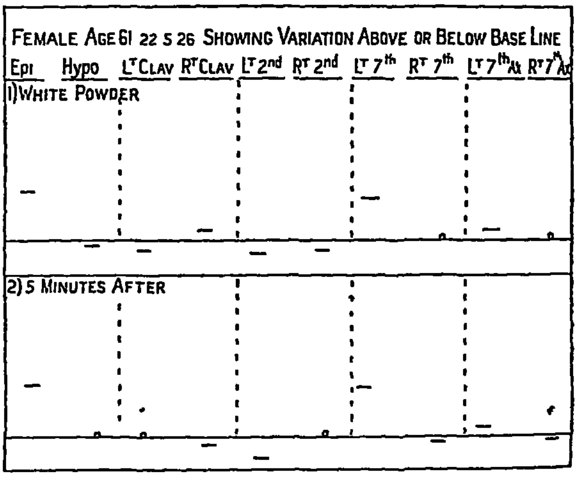
VISCERAL REFLEXES

Elevation of the thorax, especially affecting the upper part has been illustrated in the foregoing instances I propose now to deal with certain special stimuli leading to a diminished postural tone of the diaphragm shown by elevation of the expiratory level, an effect the very opposite of that recorded for the scalenes, an inhibitory action or one of increased relaxation These stimuli arise from viscera, and though the first example clearly shows an important associated effect on the thorax, with which I have chiefly to deal, the essential change is clearly in the diaphragm

Gastric Reflex

In the course of the main investigation I thought it advisable to explore the question of gastric distension, to see whether any light would be thrown on the mechanism of respiration under these circumstances The first observations were made by taking tracings of the respiratory movements, then sending the individual to get his dinner, following which a second tracing was made This showed that the epigastric movements were somewhat increased * It also showed, however that there was a tendency to diminish the movements of the upper part of the chest, and to increase slightly those of the lower part In view of these changes it was necessary to make a continuous investigation, for it is difficult as I have indicated above to get the subject into precisely the same position on each occasion and such differences might well have arisen from slight alterations of posture Accordingly the old method of distending the stomach with a seidlitz powder, in which the two halves were given separately, was adopted, and a continuous tracing was obtained This showed an elevation of the epigastrium following the rapid distension of the stomach * It also showed that the thoracic wall on the left side was protruded to a relatively great degree amounting in some instances to a total movement of two inches The record was taken from (1) the clavicle, indicating elevation of the thorax, (2) one of the upper ribs selected from the second to the fourth, (3) one rib from the lower chest complex sixth to the eighth rib and (4) a point taken in the axilla between the eighth and twelfth ribs, these four points being combined to form a single tracing of the left or right side The right side always moved outwards to a less extent, and sometimes not at all A further stage in the investigation necessitated the introduction of a series of U tubes containing liquid into the recording apparatus, in order to estimate the alteration occurring at each of the four points mentioned, and in the epigastrium and hypogastrium

FIG 3.



Changes occurring after the administration of a seidlitz powder in two separate portions Short lines indicate the relative elevations or depressions above and below base line

By this means certain constant phenomena were found (1) in the elevation of the epigastrium, and (2) the forward movement, eversion, of the lower chest complex on the left side As regards the movement of the right lower chest complex, this varied, as a rule, very little or no protrusion occurred, but in any case, the movement was considerably less than that of the left side In the lower axilla the effects varied In some cases eversion was found to occur, the left side being more affected than the right, in others little or no change was observed, in a few the right side was actually inverted The hypogastrium sometimes was protruded, but generally remained near the initial level The effect on the clavicles (as indicating the scalene action) varied, as did also the level of the four upper ribs In general, there was a depression of both these points, and on both sides, but sometimes in elderly people the clavicles, especially the left, were elevated The eversion is least marked in normal young adults * It is more marked in the middle-aged * (Fig 3), and in the elderly * (Fig 4) is supplemented to some extent by an elevation of the left side of the chest as a whole Functional cases show a very marked eversion with elevation of the left chest—a summation effect The constant alterations shown were (1) an eversion of the left lower part of the thorax, as indicated by the protrusion of the sixth, seventh, or eighth rib in the nipple line, and (2) the elevation of the epigastrium

Dr Livingstone investigated the effect of giving the seidlitz powders to an individual while under X ray observation He traced the level of the diaphragm on the screen, then gave the seidlitz powder, and four minutes later again made a tracing Meanwhile the subject was not allowed to alter his position This was done in ten cases The results are briefly as follows There was a rise in the expiratory level of one or other side of the diaphragm in eight cases, a fall in one, and no change in the tenth This level was on the right side raised in five instances, lowered in one, and unaltered in four On the left side the expiratory level was raised in seven, lowered in two and unchanged in one The degree of inspiratory descent of the same part was on the right increased in three, diminished in two, and unchanged in five On the left side there was an increase of movement in two, a diminution in two, and no change in six. The prevalent changes, therefore are an elevation of the expiratory level of the diaphragm, more marked on the left side and no change in the degree of movement In an antero-posterior view of the chest under X rays a forward movement of the lower rib complex would not be observed

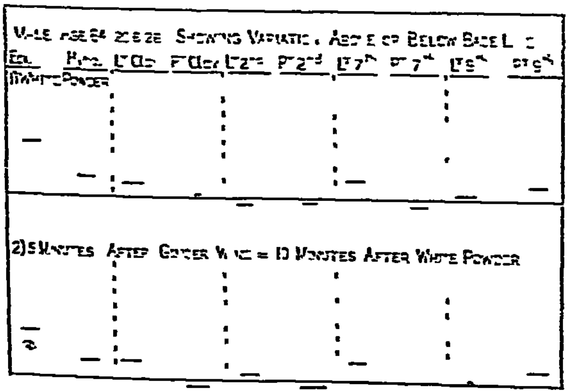
---

† The level of the left clavicle was observed in a hundred consecutive cases the individual being in the standard position The left clavicle was found to be higher than the right in 55 instances The second rib is similarly affected This elevation of the clavicle and upper ribs on the left side is due to the lack of relaxation of the anterior scalene muscle and upper intercostal muscles as compared with the muscles on the right No doubt this is a phenomenon which accompanies the visit to the consulting room, and is of a temporary nature

This reaction has also been tested experimentally by Lady Briscoe* on the cat the result being that in five cases there has been an elevation of the left side of the diaphragm and a diminution in its excursion In the sixth there was a general depression of both sides of the diaphragm, and a period in which considerable irregularity of movement of the two halves occurred. No changes were observed in the chest wall

From these investigations it is clear that a rapid distension of the stomach generally produces an effect on the diaphragm in both man and animals; this effect is most marked on the left side, tending to elevation and no increase of contraction In man this is associated with a certain amount of eversion of the lower ribs with or without elevation of the upper thorax, again more marked on the left side In the cat the chest wall is not affected. The object of accommodating the full stomach is attained by a different mechanism in man and beast How long in man this condition persists after the powder I am unable to state Some of the investigations have been prolonged for as much as half an hour, during which time a gradual diminution occurs in some instances, but is maintained in others In the cat the condition has been noted as persisting for an hour It may be contended that this alteration is a mechanical factor and is the direct result of distending the stomach, which thereby pushes up the diaphragm and pushes out the chest wall. As against this objection it may be mentioned that the abdomen was widely opened in the cat experiments, thus negativing the possibility of mechanical influences; and in the human cases, when investigated in the standard position, there was little or no contraction of the abdominal muscles To clear up this point, it was necessary to discover if other means would produce the same effect, such means not having the disadvantage of increasing, to any considerable extent the volume of the stomach. The introduction of cold liquids into the stomach frequently produces a sense of discomfort It was found an ounce of ice cold water in man,* or 10 c cm. in the case of a cat * produced the same phenomena, raising the level of the diaphragm in the cat, and everting the lower thorax in man, but to a degree less marked than the seidlitz powder; whereas, three ounces of water at room temperature produced in man only the mildest of changes from which a rapid recovery to the normal took place in the course of a few minutes The act of swallowing produces similar but transient, changes in the thorax. Dr. Livingstone could not detect any rise in the level of the diaphragm by X rays with small quantities of ice water

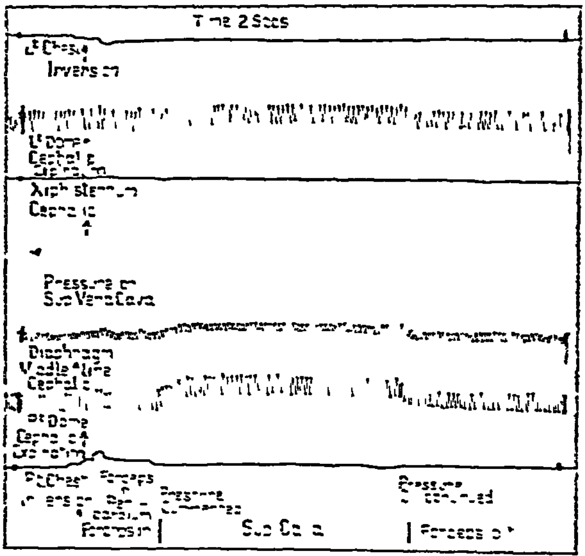
FIG 4.



Short lines indicate the relative elevations or depressions above or below base line.

I believe, therefore that we are justified in assuming that this change is caused by a reflex arising from the stomach, and owing to its prolonged operation is probably to be classified with the postural reflexes in general.

FIG. 5.



Elevation of level of diaphragm following obstruction to the superior vena cava.

Cartilages of Thorax.

It remained to investigate the mechanism by which the lower thorax is everted. A study of the thoracic bony cage will clarify the position*; the lower rib complex is formed by the sixth seventh, and eighth ribs—with sometimes, in addition, the fifth rib—between which the strong cartilaginous baulks are found. In a paper read before the Anatomical Society[20] I described the results of investigating these intercartilaginous joints, and came to the conclusion that their purpose was to assist eversion of the lower ribs These intercartilaginous joints are present on both right and left sides The numerical preponderance between the fifth and sixth cartilages on the right side was, I claimed, probably due to the presence of the liver, which was a constant factor preventing the lower ribs inverting to the full. The higher the fulcrum the greater the eversion of the lower thorax. The stomach, on the other hand, on the left side acted intermittently I concluded, contrary to the usual opinion, that these joints assisted in expansion of the lower thorax, and not in the elevation of the upper ribs I consider that the action we are now considering is a further proof of that conclusion, though at the time when that paper was written I had not begun this investigation on the stomach, and was not aware of this reaction.

This eversion is a movement, the hinge of which lies somewhere between the upper ribs, which are not protruded, and lower rib complex which is protruded. In trying to elucidate further the mechanism of this eversion of the lower ribs, the muscles of the thorax were investigated before and after a seidlitz powder in 10 cases. Eight of these were chosen at random, and two were out-patients complaining of pain under the heart; the first was a patient in whom the stomach was known to be ptosed but without marked symptoms, and the other case in which the viscera were transposed. (In the following analyses of these cases this latter one in respect of the right side acts as if it were on the left side, and is so considered.) The results of this investigation show that age is a prominent factor in the determination of the degree of this change. In the younger individuals muscular change is difficult to detect, and therefore must be slight. When detected it is of the same character as that in the older patients. In this category were four patients below the age of 24, in one of whom only a tonic condition developed in the fifth and sixth intercostal spaces on the left side.

The remaining six were over the age of 40. In four of these a tonic condition developed in one or more of the intercostal muscles of the fourth, fifth, or sixth space on the left side. Among these four are two cases who complained of pain after food ("under the heart"). The remaining two did not show this change, but on the other hand developed a tonic condition of the anterior scalene on the left side.

This result is interesting as confirming and giving a reason for the elevations as shown in the manometer readings of movements of parts of the chest as a result of rapid distension. As stated above, the duration of this action must have a bearing on this point, though I am not able to say how long this contraction persists, but I can state that at all events it persists for at least half an hour.

Where the thorax is already elevated as a result of an emotional state the addition of this gastric reflex produces a summation effect* and accordingly a greater strain falls on those muscles responsible for the sustained posture of eversion or elevation. Thus we see that a stimulus arising in the stomach causes by reflex action (*a*) an elevation relaxation in the respiratory position of the diaphragm, (*b*) an expansion of the chest, particularly of the left side, produced either by eversion of the lower ribs (in the young), or by elevation of the left side of the chest as a whole (in the old), though the actual respiratory movement of the parts is but little affected. The mechanical alteration in the chest is maintained by tonic action in muscles. This reflex I shall refer to later, as I believe it is the cause in many cases of the pain under the heart so frequently encountered.

Heart Reflex

The question naturally suggests itself, Are there other reflex phenomena in the body which produce a similar change? Dr. J. L. Livingstone and I have been investigating this point in connexion with the heart. We find that in rabbits in which the pericardium can be exposed by removing a part of the sternum, but without producing a pneumothorax so that artificial respiration is not required, manipulation of the heart produces constantly an elevation of the expiratory level of the diaphragm. The experiments have consisted in the temporary obstruction with forceps of the superior* and inferior* venæ cavæ and the systemic and pulmonary aortæ, and also in pressure on the root of the left lung by means of a bent probe. Obstruction to the outflow of blood through the aortæ produces little effect, obstruction to any of the other vessels constantly produces an elevation of the diaphragm and diminished contraction, although obstruction to the main veins of the neck does not have a similar effect. Irritation of the parietal pericardium has no such effect.

I have shown that in cats the reflex produced from the stomach affects the diaphragm only, but in man it produces an effect, not only on the diaphragm but on the thorax also. It does not seem to be unjustifiable to assume that another reflex producing identical effects in a pronograde animal will in an orthograde man having a highly developed thorax produce a similar and double effect on the diaphragm and thorax, and that as the result of cardiac conditions the thorax in man may be elevated. Such elevation of the diaphragm must be assumed to occur in acute carditis conditions so frequently accompanied by pericarditis, for in them deflation of the lower lobes is frequently found. It is common to find in severe pericarditis an epigastric recession, associated with a marked thoracic type of breathing and persistent tone in the scalenes. The former condition, due to excessive elevation of the thorax and intercostal action, is associated with a defective contraction of the diaphragm. The common factor in the deflation accompanying high paraplegia and unilateral phrenic paralysis, and in postural and postoperative deflation* of the lower lobes is a high diaphragm and thoracic elevation. The prolonged supine posture itself is normally accompanied by an elevation of the diaphragm* and increase of the transverse diameter of the thorax, especially of the lower part, indicating elevation of the thorax. These conditions are accompanied by the varying signs of consolidation. In the early stages crepitations clearing on a deep diaphragmatic breath are commonly to be detected. Such an elevation in cardiac cases in general would account for the crepitations which are heard at the bases of the lung, which are not accompanied by expectoration, and which clear up with forced and voluntary inspiration, and which may equally well be attributed to a condition of deflation of the posterior part of the lower lobes as to one of œdema.

So we see that pain and emotional states, whether temporary or of a more permanent nature, recognised as functional nervous disease, cause an alteration of breathing of the nature of a shift towards the thoracic type with raising of the expiratory level, while reflexes originating in certain viscera, the stomach and heart, result in a diminution of tone in the diaphragm associated with a persistence of tone in the muscles of the thorax. The persistence of tone on the part of the thoracic muscles concerned occurs at the expense of their resting period and must be regarded as an abnormal use or overuse.

Pleurisy.—Tonic contraction of muscles is well illustrated by the conditions which occur in pleurisy, the constant feature of which is the spasmodic condition of the intercostals in the area adjacent to the pleurisy.* In the case of a small area of acute pleurisy the easiest way to find that area over which frictions will be heard is to pass the finger down the intercostal spaces until a complaint is made of pain. At this point the muscle will be felt to be tonically contracted, and if a slight degree of pressure is maintained the pain is accentuated. No matter how the patient changes his posture the muscle still remains contracted. When measures are adopted to fix the rib the muscle relaxes, and the pain disappears in the course of a few minutes, although the frictions become more audible. In this affection the body adopts other means to assist intercostal action to limit movement. The posture assumed in bed will assist, generally lying on the affected side or inclining the spine so that the concavity is towards the affected side. In addition, however, other muscles are employed. In the case of the lower part of the chest, the lateral muscle before alluded to may become tonically contracted, as may also the respiratory part of the transversalis abdominis and the triangularis sterni.* The tonic condition of these three muscles, in the case of pleurisy affecting the lower part of the chest, is easily understood if looked at from the point of view of fixation of the ribs in the neighbourhood of the part affected. There is, still, a further method of securing rest adopted by the body. If a severe case of basal pleurisy is examined in the course of the first 36 hours* it will be found that one of the scalene muscles is in a degree of pronounced tonic contraction. In such a case all the intercostals on that side will be found to be in a condition of tonic contraction (and frequently there will be a general tenderness over the upper part of the chest). There is thus an effort to keep all the ribs on the affected side quiescent as well as to fix the chest at the upper and lower extremities. This scalene and upper intercostal tonic contraction accounts for the fact so frequently observed that the upper part of the affected chest may appear to be bigger than the normal side, at the same time it is inactive. In the course of a day or so the excessive tonic contraction of the scalenes and intercostal muscles tends to pass off. This progresses even further, inasmuch as the scalenes and upper intercostals tend to relax, and the contraction in inspiration is less than on the opposite side.* This gives rise to the flattened apex with diminished movement, the tonic condition of the intercostals in the lower part of the chest and of the abdominal muscles persists.

There is still another mechanism which is sometimes adopted in pleurisy, generally in young people, but is more constant in cases of pericarditis. This may be described as a "break" in the intercostal chain. The examination of such a case shows that the scalenes and upper intercostals on the left side are acting normally or are tonic, but that one intercostal, frequently the fourth or fifth, is completely inactive, the muscles of the lower part of the chest being in a general weak tonic condition or acting in expiration.* This relaxation mechanism adopted in the thorax may be carried to a further extreme condition, in which all the muscles acting on one side of the chest become entirely flaccid. I have met with this condition in two case of pneumonia late in the disease both of which terminated fatally. It is comparable to the lax abdomen in peritonitis and the prognosis is similar. In all these instances the contraction of muscles on the unaffected side goes on naturally.

In pleurisy we have yet another instance in which tonic contraction or lack of relaxation occurs. Observation shows that the tonic muscles are hard and taut, not relaxing and not shortening—i.e., not undergoing a movement contraction—clearly a change which deprives the muscle of its resting period.

Dyspnœa following Pleurisy

The pain of pleurisy usually does not last for more than a few days, the explanation given being that the irritated nerve-endings of the pleura are covered with fibrin and the mechanical element is removed. The extreme tonic condition of the muscles also diminishes, but in a mild degree persists for a considerable time, frequently for months, and leads to an abnormality of breathing which may produce symptoms. In pleurisy the diaphragm is known to be elevated and its contraction is diminished. Such elevation is of mild degree, and is not comparable to that which occurs with subdiaphragmatic lesions.[21] Applying the suggestion adduced in the former lecture, the explanation is that the intercostal spaces on the affected side are narrowed by muscular action, the ribs are approximated, and therefore the attachments of the diaphragm between the central tendon to the lateral chest wall are also approximated. Stretch is diminished, and so the usual stimulus produces a smaller contraction, or in some instances no response is forthcoming. This is confirmed by animal experiments.* If the condition of approximating the ribs is reproduced the contraction of the diaphragm on the same side is diminished. For reasons which I shall give, under treatment I do not think that there is any evidence of complete inhibition.

Two further points deserve attention, the first is that of the general changes which accompany old age. The second concerns the whole course of life in those who breathe in a manner which is a combination of the two extremes, and these, it should be remembered, constitute the majority of individuals. In old age because the muscles operate in the presence of defective elasticity of lung the cavity of the thorax becoming permanently enlarged, they work at a disadvantage. Which muscles will be affected depends on the type of breathing adopted, and the greater the tendency to thoracic breathing the greater will be the stress on the muscles expanding the thorax for in addition to the lung defect the costal cartilages are becoming less pliant. Two means are adopted to overcome this difficulty: (1) permanent elevation of the thorax, (2) increased expiratory muscle effort. The muscles affected will be seen by reference to my first lecture. If, however respiration is mainly diaphragmatic the difficulty is met by a lowering of the level of the diaphragm, with or without an elevation of the thorax. Thus we find in the senile diaphragmatic type either: (1) bent back and a prominent abdomen, or (2) elevated shoulders and a flat abdomen, and in the thoracic type (3) an over-distended and elevated thorax, the short-necked individual. In either of the last two a strain is thrown on the elevators of the chest. There is, however, a tendency in senescence for the thoracic type to develop a shift towards greater use of the diaphragm (type 1 above), and when this has been achieved, there is disappearance or diminution of symptoms arising from overuse of the muscles operating on the thoracic cage. The activity of these muscles will, however be renewed with dyspnœa, or under the conditions mentioned earlier in this lecture, or when calcification is taking place. It is interesting to note that calcification sets in early in life in the costal cartilages when the Wassermann reaction is positive and is, therefore an early change in syphilis. It may be well marked between 40 and 50 in this disease, whereas calcification in my series of 100 cases examined is not marked before the sixth decade is passed.

Antagonism of Muscles

The second condition may be termed antagonism. In quiet respiration, diaphragmatic and thoracic breathing are, as a rule, complementary and supplementary, and there is enough margin for comfortable respiration. When either is excessive interference with the efficiency of the other occurs. In excessive diaphragmatic breathing the lower ribs are held down by the lateral muscle approximated by the transversalis abdominis and triangularis sterni. The lower ribs are therefore, hindered in their thoracic function of being raised and everted. When thoracic respiration is excessive the diaphragm is splayed out, and its contraction is less effective and becomes still more inefficient when in addition the thorax is elevated.*[22]

A second instance of antagonism occurs when diaphragmatic and thoracic breathing are over-active simultaneously. With the intercostal muscles acting strongly in inspiration to elevate and evert the ribs, the triangularis sterni and transversalis abdominis are approximating the costal margins in the epigastrium, and the lateral muscle is depressing the lower ribs. There is, therefore, an excess of work thrown on to the intercostal muscles, and a strain which is aggravated with loss of elasticity in the ribs.

Analogous to the last described condition is the effect of contraction of the abdominal muscles which function as muscles of posture especially the rectus abdominis and that part of the external oblique attached to the sixth–ninth ribs. These muscles serve to connect the chest and pelvis, and when in contraction tend to oppose the elevation by the intercostal muscles of the ribs to which they are attached. In both these latter conditions the strain tends to fall on the points of junction between the upper and lower parts of the chest—i.e., in the region of the fifth and sixth ribs.*

To sum up this lecture, certain states of mind, certain somatic and visceral stimuli, senescence and respiratory stress produce changes in the mode of breathing. These changes entail undue activity on the part of certain muscles, which activity I believe to be generally of the nature of enhanced and persistent tonus. This occurs at the expense of the resting period of these muscles. If transient, it may not be of moment, but if persistent it will soon produce exhaustion. Activity in muscles calls for a vast increase in blood flow, and in the case of repeated movement (phasic) contractions this is provided by direct massage to the capillaries and veins. Persistent tonic contraction, so far from helping the circulation, actually impedes, so that exhaustion ensues leading to distress. Distress is appreciated by the patient as pain, and calls for investigation and treatment.

(The bibliography, to which references are given in this lecture, will appear with the third lecture.)

LIGHT TREATMENT IN SURGICAL TUBERCULOSIS *

By Sir HENRY GAUVAIN, M D , M Ch Camb ,
MEDICAL SUPERINTENDENT, LORD MAYOR TRELOAR CRIPPLES' HOSPITALS, ALTON AND HAYLING ISLAND

This paper is based on experience in sun and artificial light treatment in surgical tuberculosis at the Treloar Cripples' Hospitals at Alton and Hayling Island The remarks which follow should be taken as restricted to the general light treatment of surgical tuberculosis, and not necessarily as referring to other conditions to which phototherapy might be applied

It is important to inquire why the results of light treatment in surgical tuberculosis are so variable, why, in some instances so brilliant, and in others so disappointing If we could explain these differences we should be in a better position to conduct treatment with promise of success I, therefore, would place before you a theory which attempts to explain these variations For want of a better term I shall call it the " theory of varying stimuli and varying response " It may, at any rate, form a working hypothesis as a guide to treatment

Sunlight not a Specific Treatment

Contrary to what has been stated elsewhere, the sun will not cure all forms of surgical tuberculosis In my opinion it is in no sense a specific treatment At the best it is usually merely an aid to, and an accelerator of, cure, and only to a limited degree should it be used as a substitute for other means of treatment Its employment should supplement not supplant other means of cure Nevertheless, as an aid it is often of unique value Treatment by light may be general or local, or both, and the source of light may be solar, from artificial sources, or a combination of both By the majority general treatment by natural sunlight is considered the best form of light treatment available I hold the view that the best type of general light treatment to adopt will depend on the nature of response of the individual concerned

Here let us first briefly consider where sun treatment fails If, as alleged, the sun will cure all forms of surgical tuberculosis, why is it that it not only will not prevent infection, but also will not cure the disease in subjects living in the most sunny districts ? It is well known that tuberculosis will readily infect and rapidly slay unimmunised native races living under apparently the most ideal conditions from a heliotherapeutic standpoint Islanders residing near the equator, enjoying an equable climate, where the native may live nude all the year round, exposed to and enjoying sunlight of high actinic value, may rapidly die from the disease It may be argued that the hygienic conditions are bad, and that they have not acquired immunity But relatively immune resident Europeans becoming infected and who live hygienic lives will not necessarily or even probably be cured under these conditions, so apparently perfect for heliotherapy They will almost certainly do better if they return home I am not now alluding to localities such as central or southern India, where the excessive heat renders sun treatment of only very limited application Were light a specific treatment for tuberculosis, we might reasonably expect that the onset and progress of the disease might be prevented under suitable heliotherapeutic conditions This is contrary to fact

Consider the much-lauded Alpine climate Tuberculosis is endemic in Switzerland It has even been found desirable to establish a special sanatorium for university students Tuberculosis will arise and develop in sun-cure stations in the Alps More than that, it may even progress to a fatal termination in a person resident at such a station who has there acquired the disease and has had heliotherapeutic treatment *ab initio* Bernhard, though extolling the value of the high mountain sun, quotes Sauerbruch, who draws attention to (what Bernhard calls)—

> " The remarkable observation that swollen tuberculous glands in children who live in the high mountains will not heal up in spite of the sun and direct radiation, but rapidly improve at sea-level or when treated by brine baths in the plains "

Bernhard adds that he will not deny that such cases occur Such an admission is of extreme significance. Nevertheless, and rightly so, those who employ heliotherapy generally become enthusiastic as to its value

How may we explain this apparent paradox ? I submit that no reasonable explanation has yet been offered by the scientific investigation of demonstrable effects of ultra-violet or other forms of light Sonne's statement that the value of light treatment is dependent largely on its thermal effect is not adequate The function of ultra-violet light in raising hæmo-bactericidal power, though of some significance in certain cases, does not furnish the clue Indeed, in man, hæmo-bactericidal action on specific organisms may at times be so high that it cannot further be appreciably raised, and may even be lowered after exposure Moreover, this action is obtainable by other means, and is not peculiar to light therapy Consideration of alterations in the chemistry or composition of the blood and other changes which may follow irradiation of the skin does not very materially help us Indeed, no known sequel to successful irradiation, either from sunlight or artificial light, affords any completely satisfactory explanation How then can success or failure, following systematic light treatment in surgical tuberculosis, be reasonably explained ? I have already indicated some results of insolation These, combined or singly, doubtless have a bearing, but they do not tell the whole tale Let us consider the subject on broader lines and not permit our attention to be diverted by certain known sequelæ to insolation

Consider a patient receiving suitable insolation in this country Such treatment naturally implies treatment of the nude body in the open air under conditions which have seasonal, and indeed daily and hourly, variations The intensity and character of the solar radiation varies with the angle of incidence of the sun's rays, the density of the atmosphere through which they penetrate, the purity of the atmosphere, the presence in the air of moisture, dust, or smoke, the amount of sky shine and of reflected light, the intervention of passing clouds Moreover, latitude, locality, altitude, climate, temperature, direction and force of wind, proximity of sea, mountains, rivers, or lakes, forests, fields and even the nature of the soil, are all factors not to be neglected

Factors for Success in Heliotherapy.

At once we see that sun treatment, wherever undertaken, must be administered under continually changing conditions even when applied in one particular district The intensity and the character of the light available for therapeutic purposes are subject to perpetual change It is true that the extent of these variations differs much in different localities, but the one common unchanging factor is that of constantly changing conditions I would go further, and say that it is perhaps a most important factor Sun treatment for its general effects in surgical tuberculosis, is more effective in the constantly changing conditions—not merely solar—found in temperate climates than in the comparatively more stable conditions found in many tropical regions, where the intensity of the light may be much greater and not subject to such diversified actinic variation

Moreover there is great diversity of response in the individual being treated That is true, however, whether he receives sun or artificial light but in the latter case while individuals may vary, the light applied and the other factors are usually approximately constant

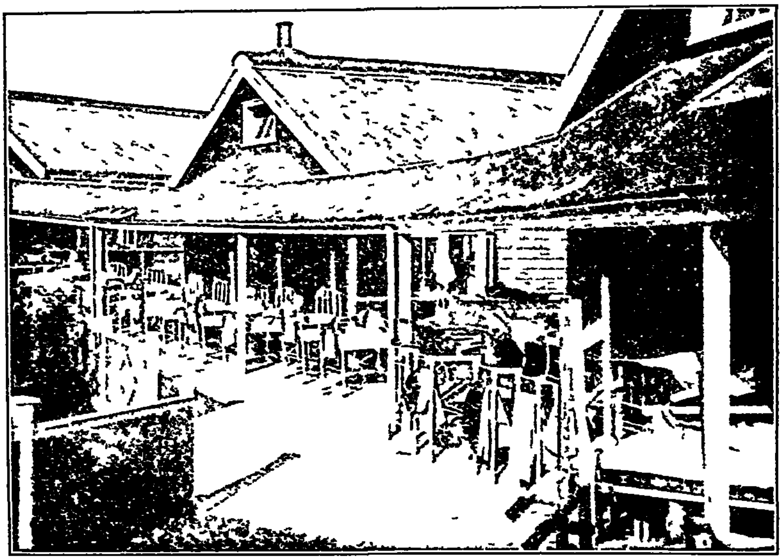
---

* Being the opening paper of a discussion before the Section of Electro therapeutics of the Royal Society of Medicine on Jan 21st 1927 Numerous lantern slides were shown in illustration

The more one considers the alleged superiority of sunlight over artificial light in the treatment of the subject attacked by surgical tuberculosis, the greater becomes the conviction that this superiority is due, not so much to the intensity of the light as to the variations in character and intensity of the light, assisted by changing external conditions not directly due to light In addition, in the case of a single individual responding satisfactorily to insolation, there is both a seasonal and a daily variation in response A lengthy clinical experience has taught me that I may reasonably expect the greatest seasonal response in the spring and early summer This is the period of greatest vegetative activity Vegetation dormant during the relatively dark winter has enjoyed a period of rest, and now eagerly responds to the light stimulus which it receives As the summer advances it is unable to respond so vigorously to the stimulus which, though present and perhaps more intense, is less effective Similarly with the patient His greatest power of response to the stimulus of light may be anticipated after that period when he has received the minimal stimulation And in practice we find the greatest progress made is in May and early June, not in July and August when the light intensity may be even greater, and when also the patient is able to tolerate longer exposure This is not a mere question of skin sensitivity, but of seasonal response

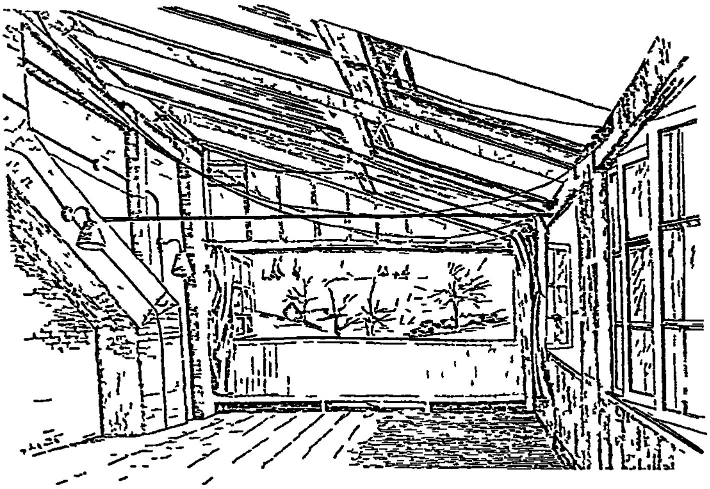
Realising this fact one is able to evoke increased response, if one deems it wise to do so, by changing the character and intensity of light and associated stimuli Thus, with patients responding well up to July but who are then commencing to flag and whose progress is less rapid, I find acceleration is again obtainable if I transfer such cases from Alton to Hayling A new type of stimulus produces a notable acceleration of improvement in the patient capable of making the desired response The basal metabolism is enormously increased by sea-bathing, spraying, paddling, cool sea breezes, and assistance given by the altered character of light The different intensity of the light will not alone explain the change, the combination of altered stimuli will Progress again becomes rapid provided stimulation is not pressed beyond the patient's capacity of response In other words, given a minimum light value, the benefits of insolation may be ascribed not so much to the intensity of the light as to the shock of varying stimuli (light and other) eliciting favourable responses The optimum light value will vary with individual patients

FIG 1.



Light and shade Balcony at Alton

FIG 2.



End of a sun balcony, showing the sliding roof of vitaglass, folding windows and flap ventilators at floor level

It is unnecessary for me to discuss the harmful effect of prolonged intense stimulation The patient is unable to make continuous response In the effort he becomes exhausted, irritable, nervous There is a practical significance in this observation. Continuous exposure to sunlight in the summer will not produce beneficial results as speedily as alternations of light and shade, of heat and cold, of humid and dry air Even the onset of a week or so of rainy or cloudy weather may be an advantage to the sun-cure in a hot summer Alpine writers would have us believe that Alpine sun in Alpine conditions is best of all I disagree It is only true for those patients in whom such stimuli will produce the optimum response Excellent results have been obtained in the Alps, but if these be analysed and compared with results obtained at home, we need not fear the comparison I am constantly seeing patients who have been wise enough to return from Alpine stations because progress has been arrested and in whom, in many cases, there are signs of exhaustion and retrogression of the disease Where the Alpine climate and conditions are really helpful is in the case with much recuperative power capable of responding to intense stimulation In these rapid and striking initial progress may be anticipated until power of response becomes exhausted The dramatic improvement obtained in such cases encourages many totally incapable of such improvement to essay the same cure I regard it as deplorable that so many patients are sent so far afield who would often do much better by remaining at home The progress which may be anticipated by treatment in the Alps does not so much depend on the extent, activity, or nature of the lesion, or the presence of complicating abscesses or sinuses as on the individual power of response The cachectic, non-pigmenting patient, of low resistance, even with the most trifling lesion will not do nearly as well under such conditions as if he were to remain at home The same is true for young children or elderly people, who rapidly become exhausted, and are unable to respond to the excessive stimulation they are called upon to receive (See Fig 1)

Sun Balconies for Use in the English Climate

In the winter, progress of the individual is often delayed This is not entirely due to the lack of sunshine available. In part it may be due to a natural slowing down of power of response. Resistance is lowered, Nature, to some extent, resting At the same time, the English patient is often not subjected to stimuli which have been available during the summer months These may, however, be supplied partly by natural and partly by artificial means. The following is a practical method which I have employed at the Morland Clinics, Alton I have there constructed balconies with sliding roofs of vitaglass This glass is said to transmit ultra-violet light of the wavelengths found in the solar spectrum Naturally, some especially of the shorter-waved rays will be absorbed and their intensity diminished. To ensure maximum transmission of light, the glass must be kept clean, a precaution frequently overlooked By the use of this glass considerable assistance is afforded to heliotherapy in this country when, owing to cold or rain, exposure to the naked sun or to sky shine is impracticable

As these balconies have proved of great practical help to me I here illustrate one (Fig 2), as I conceive their general adoption might be of substantial help to other clinicians That half of the roof adjacent to the wall is permanent and glazed with vitaglass The distal half consists of sliding panels of vitaglass suitably counterpoised and so constructed that they may readily be drawn up either entirely under the fixed roof or drawn down, or will remain stationary in any intermediate position at will Thus, if it rains these panels are lowered and patients may still be exposed nude to the sun or sky The visible and heat rays are transmitted and give ample illumination and usually sufficient warmth In fine weather the panels are raised and direct insolation proceeds The walls above the level of the beds are constructed of folding glass panels which may either be completely opened or completely closed, or occupy any intermediate position Ordinary glass is here all that is needed Whenever possible both the windows are folded open and the vitaglass panels drawn up The walls, six inches from the floor, are made of hinged flaps which open outwards so that air but no rain shall be admitted, these, in conjunction with suitable louvres in the roof, ensure perfect ventilation even during driving rain and when it is desirable to have the roof down and the folding windows closed By means of suitable blinds, shade may be obtained during hot summer days, and when light treatment is intermitted They also serve the purpose of excluding moonlight On another balcony, in a specially sunny situation, the fixed portion of the roof is constructed of Calorex, a glass which absorbs the greater part of the heat On this balcony the patient may be in bright direct sun or pleasant cool shade at will Artificial light is installed to supplement natural light when the latter is deficient Thus augmented light treatment with aerotherapy is available under natural conditions at all seasons of the year The principle of varying stimuli, to which I attach so great importance, is maintained, and the intensity and character of the light treatment may be varied at will The artificial light employed therapeutically is novel in character, but being still in the experimental stage, its description will be deferred for a later communication

Diurnal Variations in Individual Response

While there is a seasonal variation to the response of any given individual to light stimulation, there is also a diurnal variation. It has long been recognised that morning light is most therapeutically valuable. This, in my opinion, is not due solely or even chiefly to the nature of the light, but, because the light-shock evokes a greater response as immediately following the darkness necessarily antecedent, Rollier amongst others has emphasised the value of morning light

I have indicated that there are seasonal and diurnal variations in response to light stimuli in the same individual. Still more marked are the variations in response to such stimuli in different individuals I am not here concerned so much with special reactions, such as may be demonstrated in the treatment of rickets by light Rather am I attempting to visualise the total responses to exposure clinically noticeable in the subject of surgical tuberculosis These responses not only vary with each individual, but also to some extent with the type of the disease

If we expose half a dozen different patients to a similar source of radiation, sun or artificial light, or a combination of the two, for a shorter or longer period, the sum total of each of the individual results will be found to vary within wide limits, as evidenced both by the appearance of the patient and the rate of progress towards recovery Neither is it possible, by altering the time of exposure of these different patients, to attain the same improvement in all, or as will be shown by that patient making the greatest improvement under the optimum exposure The power of total response varies widely Scientific heliotherapeutists with physical leanings urge that we should know the intensity of the light we employ in the different regions of the spectrum Physiologists insist on the significance of the biological reactions to light, but there is no evidence that the sum of the biological responses evoked will be similar in each individual irradiated by identical light under precisely similar conditions Indeed, all clinical evidence with which I am acquainted in surgical tuberculosis would lead to a contrary view Viewed clinically, the different responses in different individuals seem almost infinitely variable That it is desirable to have exact knowledge of the nature of the light employed and of the various effects which it will produce in the organism is undoubted, but I am forced to the conclusion that a correct clinical estimate of the total effect produced is of greater value in treatment than exact information of certain reactions, though I emphasise the desirability of this information where procurable Heliotherapy in surgical tuberculosis is truly still more an art than an exact science.

The Chief Factor in Raising Basal Metabolism.

It has been repeatedly reiterated that sun-exposure results in increased metabolic activity and this increased metabolism has been attributed to sunlight Leonard Hill and Argyll-Campbell, working at Alton and Hayling Island, have shown conclusively that a constant rise in the basal metabolism occurs after a course of sun treatment, but that this rise is due to exposure of the nude skin to cold air, not to sunlight It occurs either in shade or sun and is, as might be expected, greater in winter than summer Alpine writers attribute this effect to sunlight That is incorrect

Basal metabolism is commonly higher in patients treated in the Alps than in lowland districts because they are more exposed to cold, but now the mechanism of its production is understood it may be equally *raised independent of locality* Moreover, there is an optimum limit to metabolic activity varying with the individual I am convinced that the high basal metabolism produced by exposure to excessive cold as described by Leonard Hill in some shivering Alpine children is not only not beneficial but actually harmful To maintain it is both cruel and undesirable A raised basal metabolism controlled within proper limits suited to individual requirements is advantageous It means the exhibition of energy production Heat is generated internally and lost from the body This necessitates the ingestion, digestion, and absorption of more food. It implies increased oxygenation, tissue change, and elimination of waste products. Associated with this is a speeding-up of repair in damaged tissues. But there is a limit beyond which this additional strain on the patient should not be attempted. The very young or old, the weak and cachectic, cannot successfully undertake such extra work. For these such rigorous treatment, inseparable from the winter cold even when associated with sunlight, is contraindicated. Especially is the strain harmful if protracted. If such a reaction is desired, it is better obtained as a series of progressively increasing shock stimuli than by continuous exposure, and in no way are these stimuli better obtained in suitable subjects than by graduated paddling, spraying, or immersion in sea-water. In those who are able to respond suitably the glow of reaction after a sea-bathe, the tingling of the skin, the sense of exhilaration and well-being, the increased appetite and power of assimilation of food, and the associated appearance of robust health, are evidences of the benefits of this stimulus. While the average basal metabolism of our resting, nude, recumbent patients at Alton is 40 per cent. above the normal, during a sea-bathe at Hayling it may be raised to 1000 per cent. above normal, and its value is reflected in the improvement observed in patients suitable for such treatment. The food cost per head of patients at Hayling receiving such treatment is nearly double that of similar patients at Alton. They need, consume, and utilise more food to do the necessary extra work they are called upon to perform, and the value of such work is reflected in the more rapid repair of healing lesions. But such additional work should be only demanded from patients capable of usefully making such effort, and we therefore only select such patients for this treatment as may be expected to respond suitably to the stimulus. The very young or old, the very weak or toxic and cachectic, in fact, the very ones whom we especially desire to aid are those incapable of responding to the strain such treatment necessitates. For these, the high Alps and the seaside are contraindicated. Much as we desire them to progress, we must of necessity be patient and content with the more gentle stimulus obtained inland.

It is noteworthy that though the incidence of tuberculosis is diminishing, tuberculosis in this cachectic type has been, during the last few years, increasingly evident in my experience. I attribute this to children born during the war who, owing to dietetic and other reasons during the pregnancy of their mothers, and during their own infancy are endowed with lower resistance to disease than the ordinary child. They have been more readily infected and possess less power to resist implanted tuberculosis. This type of patient is, as one would naturally expect, more common as you descend the social scale. In establishing our marine branch hospital at Hayling Island I had been largely influenced by the hope of especially aiding this type. In practice I have found that exactly the contrary meets their case. Gentle stimuli are all they, at first at any rate, can suitably respond to. Without, as far as I am aware, having appreciated these reasons for doing so, Reyn has endeavoured to provide the bathing stimulus in the artificial light treatment administered at the Finsen Institute, and after the general light bath invariably submits his patients to a cold or tepid douche. I do the same.

To return to light treatment proper, permit me to illustrate my thesis by perhaps an extreme example, none the less valuable because recorded by an astute lay observer. The Comte de Tressan thus describes a visit he paid to the celebrated author of "Gil Blas" who was then aged upwards of 80 years:—

> "I had been apprised not to visit M. le Sage till near the approach of noon, and the feelings of that old man showed me the effect which the state of the atmosphere produced in the melancholy days of bodily decline. M. le Sage awakened every morning so soon as the sun appeared some degrees above the horizon, became animated, acquired feeling and force in proportion as that planet approached the meridian, but as the sun began to decline, the sensibility of the old man, the light of his intellect, and the activity of his bodily organs began to diminish in proportion, and no sooner had the sun descended some degrees under the horizon than he sank into a lethargy from which it was difficult to rouse him." (M. le Sage died in the winter of 1746-47.)

In such a case a feeble light stimulus was sufficient to produce an optimum response. Had M. le Sage been suddenly exposed nude to the Alpine sun, under Alpine conditions, the shock would probably have been fatal, while to a lusty young infected adult with good resistance it would be the best possible stimulus to apply.

I have said enough to show that at this stage of our knowledge, exposures to light should be gauged by the estimated power of responses as judged by clinical experience. It may be said that this is empirical and unscientific, but I maintain it is correct. It is pursuing a false ideal to attempt to estimate individual requirements by mere physical measurements of light intensity or the observation of isolated physiological effects. I have seen both elderly and very ill people harmed irreparably by light treatment given by rule of thumb in doses applicable to healthy adults, but totally unsuited and much in excess of their especial needs. Clinical observation and experience are our best guides in the art of heliotherapy at this stage of our knowledge.

Pigmentation

I should here make brief reference to the rôle of pigmentation of the skin following sun treatment. Its value has been denied, but shrewd clinical observers like Rollier testify to its utility. With them I agree. It is valuable because it has a protective function. Longer exposure to light and cold can be tolerated and, if such exposure is correctly timed, is advantageous. Pigmentation is not necessarily synchronous with amelioration of disease, though it frequently is so. A pigmented patient may be so severely infected that nothing will save him, but that is not the fault of his pigment. Moreover, when a patient is well pigmented, erythema, one of our useful aids to dosage, is lost and an unskilled practitioner may make errors in exposure, but that is the fault of the physician. As a general rule, a well-pigmented subject can tolerate and benefit by longer exposures to light and cold air than a non-pigmenter, and the danger of error is diminished.

There are some good pigmenters who do not respond successfully to insolation in spite of every care in its administration. In those it is well to review our other methods of treatment and satisfy ourselves that nothing is amiss. In such patients light treatment should probably be more intermittent and the effect of increasingly strong shock exposures ascertained. Quite likely much stronger or weaker stimuli than have been given are needed. If these investigations are made carefully, the number of good pigmenters not responding properly will be found to be reduced when errors in one or other method of treatment are eliminated.

From a consideration of the above it may be inferred that general artificial light treatment for surgical tuberculosis owes much of its lack of success to the non-recognition of fundamental essentials. Constant intensity of light with regular exposures under the stable conditions found in a light department cannot be expected to produce optimum benefits. A certain minimum of light varying with the individual may be considered as essential for the conduct of light treatment, but after that, greater importance is attached to varying intensities and times of exposures, in this way, simulating more nearly light therapy under natural conditions.

Local light treatment of superficial lesions is governed by entirely different rules of application. It is administered to produce a direct reaction to a definite stimulus. As an example, lupus vulgaris may be instanced where local light is of value by its direct bactericidal action, its thermal effect, and the local favourable inflammatory response which suitable exposure elicits

In conclusion, it may be urged that the value of general light treatment in any particular district depends only partially on the intensity and nature of the sunlight available For some individuals very intense light is the reverse of beneficial, particularly in feeble cachectic patients with little power of response What is of greater importance is the application of varying light and other stimuli, graded and varied according to individual needs Patients able to respond well will do well under intense stimulation, whereas for weaker cachectic, and elderly patients great caution should be exercised and only slight stimulation is at first appropriate

If the inferences I have arrived at from a study of sun treatment are correct, it would appear that the search now being made for a suitable therapeutic artificial light of constant character and intensity, readily measurable by physical means or by individual biological responses, and constant in application, is illogical, and clinical evidence supports this view Rather should we adopt the method of varying stimuli graded to produce optimum responses in individuals who are themselves susceptible to infinite change in reacting power It is on these lines I am now directing experimental work

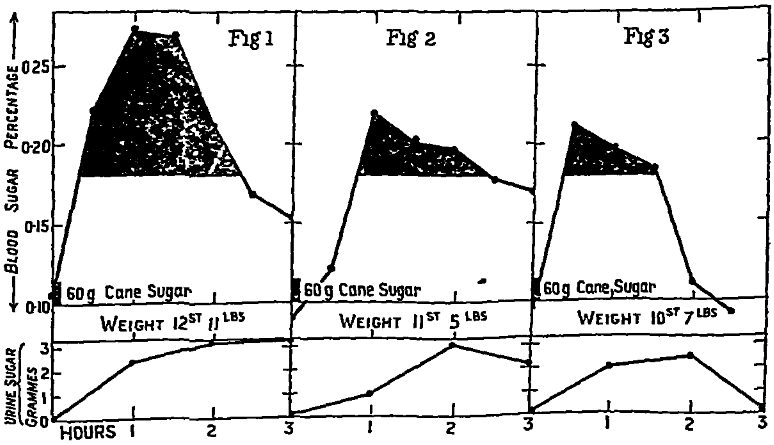
To one other response I should like to make passing mention All observers have been struck by the valuable psychological action of light as evidenced by the cheerfulness and vivacity of the suitably insolated subject Light is a tonic both to the mind and to the body and its effect in stimulating mental activity is one of the most interesting and not the least valuable phenomena associated with the complex and fascinating sequelæ following light therapy in surgical tuberculosis

GLYCOSURIA COMPLICATED BY GALL-STONES.

BY C D SHAPLAND, M B, B S LOND,
RESIDENT PHYSICIAN, RUTHIN CASTLE

THE following case presents much that is of interest both from the theoretical and practical point of view, and is therefore thought to be worthy of publication

T J D, a storekeeper, aged 56, was admitted to Ruthin Castle in March, 1926, *complaining of fatigue*, the passage of large quantities of urine and glycosuria—the latter was first discovered eight years previously and had been present constantly ever since despite dietetic measures Six years ago he had an attack of acute abdominal pain diagnosed as gall-stone colic, there was a further attack two years ago, and one mild one since



On examination the patient, who was a flabby, obese subject, presented no physical signs of disease beyond a sluggish reflex in the right upper quadrant of the abdomen and slight tenderness over the gall-bladder Radiological examination of the gall-bladder region showed that this organ had a uniformly dense fundus with several opacities in the region of its neck

The usual routine employed at Ruthin Castle in the management of a diabetic patient was followed in this case For 48 hours he was kept on a *diet similar to that which he had been* taking before admission—viz, C 40, P 106, F 142 (calories 1920) The blood-sugar was estimated night and morning at 6 P M and at 8 15 A M, the urine collected for 24 hours and the quantity of sugar estimated Although the blood-sugar on this diet remained relatively low—0 14 per cent —the urine-sugar amounted to over 15 g in each collection Patient was therefore fasted for 24 hours, but, despite the fact that the blood-sugar fell to 0 09 per cent, the urine did not become sugar-free A "ladder" diet was then instituted, the carbohydrate being kept very low, and, as he was so much overweight for his age and height—namely, 2 st 9 lb —the diet was not raised above one of 1110 calories, C 8, P 80, F 81 On this diet, combined with massage and Vichy massage on alternate days, the patient steadily lost weight, but the urine failed to become sugar-free—from 2 to 7 g being lost daily in the 24 hours' collection The use of insulin was contra-indicated as the blood-sugar was now keeping at a normal level averaging about 0 12 per cent

A carbohydrate tolerance test done about this time (Fig 1) gave a typical diabetic type of curve, and an iodeikon test confirmed that the opacities in the gall-bladder region were actually in the gall-bladder

It seemed probable therefore, that the patient was *an atypical case of diabetes mellitus—atypical* in that with a normal blood-sugar there was a constant loss of sugar in the urine Renal glycosuria was ruled out by the carbohydrate tolerance test (Fig 1) which showed a true defect in dealing with excess of carbohydrate The association of chronic pancreatitis with infective conditions of the gall-bladder and its ducts has long been established, it seemed probable, therefore that the gall-bladder disease was the cause of, or at any rate was aggravating, the diabetic condition, and for this reason operation was advised.

Preparation of Patient —For several days before the operation patient was kept on a diet liberal in carbohydrates but restricted in fats (C 70, P 40, F 50, calories 920), in order to lessen the danger of acidosis from incomplete oxidation of the fats

Operation —This was performed under gas oxygen, and ether anæsthesia by Sir Berkeley Moynihan The liver was small and tucked away beneath the right costal margin, the gall-bladder was shrunken, a large stone was palpated at the fundus, and several small ones in its neck The pancreas felt hard and indurated Cholecystectomy was performed Patient stood the operation—which was technically a difficult one—well, and at no period of the operation gave cause for anxiety The gall-bladder, which was small, had a thick fibrous wall and contained a large stone of putty-like consistence at the fundus with three smaller stones of a similar nature in its neck A culture taken from the interior of the gall-bladder directly after operation gave no growth on blood-agar or on a MacConkey plate, and a culture from the interior of the large stone gave no growth in broth The blood-sugar before operation was 0 12 per cent, immediately after it had risen to 0 24 per cent Six units of insulin were therefore injected, and thereafter blood-sugar estimations were made hourly—after five hours *the blood-sugar had again fallen to 0 12 per cent*

Post-operative Treatment —The first 24 hours after operation patient was kept on rectal salines every four hours—each injection being of 10 oz and containing 10 per cent glucose with 1 drachm of bicarbonate of soda, in addition alkaline water was given as required by the mouth Blood-sugar figures on this day were 0 15 per cent and 0 21 per cent, urine-sugar 27 1 g, and acid bodies 4 3 g, 14 units of insulin were given in two doses of 6 and 8 units respectively On the second day 6 oz liquid feeds were given two-hourly, these were chosen from water, lemonade, milk, milk and water, and weak China tea Each feed contained 5 g of sugar so that a total of 60 g of sugar was taken in the 24 hours, in addition alkaline water was given as required, a total of 240 gr of bicarbonate of soda being taken in the 24 hours On this day blood sugar figures were 0 16 per cent. 0·19 per cent., urine-sugar 22 g., and acid bodies 1·5 g. Insulin was given in two doses of 6 units each.

During the following 15 days patient was kept on a diet relatively high in carbohydrate value but restricted in fats —viz. C 45 P 45, F. 40, calories 740 Twelve units of insulin were injected daily in two doses of 6 units: the blood-sugar varied during this period between 0·13 per cent. and 0·18 per cent. and the urine-sugar between 2 and 5 g. Acid bodies which on the day of operation amounted to 5 g. dropped to unestimable quantities on the fifth day, to traces only on the tenth day, and finally disappeared on the fourteenth day after operation. Two days after the last trace of acid bodies had disappeared from the urine, the carbohydrate in the diet was dropped from 45 to 10 g., and for the first time for eight years sugar disappeared from the urine. Patient was then fasted, insulin omitted and a "ladder" diet again instituted. The carbohydrate intake was raised to 30 g. without any return of glycosuria, but the fats were not pushed beyond 80 g. as he was still somewhat overweight. A carbohydrate tolerance test done at this time (seven weeks after operation) showed a considerable improvement in the form of the curve (Fig. 2)

The patient was discharged on a diet of C 36, P. 65, F. 83, calories 1195 blood-sugar figures on this diet varied between 0·10 and 0·12 per cent. and the urine kept sugar-free without having further recourse to insulin.

Discussion.

In the majority of cases of diabetes mellitus the renal threshold for sugar becomes raised: this case is unusual in that a true defect in carbohydrate storage has been associated with a very low renal threshold. In addition the case was complicated by a diseased gall-bladder and a marked degree of overweight. According to Joslin and other authorities it is becoming increasingly evident that gall-bladder disease bears a distinct relationship to the essential pathology of diabetes, it seemed rational, therefore, to advise operation in this case. The methods adopted to combat acidosis by giving a diet liberal in carbohydrates but restricted in fats before the operation, with plenty of fluid, sugar, and insulin with blood-sugar control for several days after operation have been described—the successful issue has been mentioned.

Eight months later this patient was free from all symptoms of the disease his fatigue had gone, the urine had remained sugar-free, and he felt strong and well On a diet of C. 40, P. 65 F. 85, calories 1220, the blood-sugar figures varied between 0·10 per cent. and 0·13 per cent., the urine was sugar-free, and a carbohydrate tolerance test gave—for his age—a normal type of curve (Fig 3). His weight had dropped to 10 st 7 lb—i e., about normal for his height and age Although the loss of the 2 st 4 lb. of overweight must materially have benefited his general metabolism, yet it seems probable that it was the removal of the diseased gall-bladder which was the deciding factor in alleviating the diabetic condition.

Clinical and Laboratory Notes.

TWO CASES OF ABDOMINAL ABSCESS

ILLUSTRATING THE VALUE OF ANTISEPTICS

By Sir John O'Conor, K.B.E., M.D., B.Ch. Dub.,
SENIOR MEDICAL OFFICER TO THE BRITISH HOSPITAL,
BUENOS AIRES

The following cases are recorded as a small tribute to the work of Lord Lister —

Case 1.—A girl, aged 19 was admitted to hospital suffering from appendicitis which had commenced acutely ten days before. The pulse-rate was 110 and the temperature 102° F.

Operation was performed immediately after admission. The skin was disinfected with warm formalin lotion (1 in 300) followed by alcohol sublimate solution (1 in 1000) When the abdomen was opened a large iliac pelvic abscess with an almost intolerable stench, had to be evacuated The appendix—which was disorganised and enshrouded in a peritoneal fossa—was clipped off after application of catgut ligature to its base. The huge cavity was then mopped as dry as possible and stuffed with large rolls of gauze wrung out in fresh iodoform emulsion. The upper segment of the "vertical" wound was closed by three interrupted through-and-through double silkworm-gut sutures Two similar sutures were introduced into the lower portion, their ends were knotted together, and they were left alongside gauze rolls as waiting sutures.

The gauze soaked in stinking pus was removed on the second morning and low level "peroxide carbolic" irrigation was done three times a day with "perchloride" fomentation dressing By the seventh day there was no further smell or discharge of pus although in the depth of the wound a necrotic looking cæcal wall was still in view On the eleventh day the wound had no pus in it and had bright red granulations around the parietal opening the gut was still of a dirty white colour but was dry The closed segment had united by first intention and the three silkworm-gut sutures were absolutely clean, without even a drop of serum or sign of irritation around the stitch holes. The two waiting sutures were in a similar state

On the twenty-first day, the wound having granulated sufficiently (without intestinal perforation), the sister partially closed the open crater with the two waiting sutures which had preserved their aseptic condition. The three upper sutures had been removed on the sixteenth day.

From the seventh day the five silkworm-gut (double) sutures had remained innocuous in an apparently normal white skin which had previously been swamped in mephitic pus, but which, for 20 days afterwards had been frequently saturated with warm peroxide solution (1 in 17) and carbolic (1 in 70), and dressed with lint wrung out in hot corrosive sublimate solution (1 in 3000)

Case 2 —At the same time there was in hospital another case giving striking proof of the value of antiseptics A young man was operated on for subacute appendicitis, and a small abscess was found presenting on the under surface of liver The lower segment of the parietal wound was closed by interrupted through-and-through silkworm-gut: the hepatic cavity, having been cleaned out, was first week drained by large rubber tubes At operation two silkworm-gut waiting sutures had been introduced in upper segment.

On the eighth morning as a drainage tunnel appeared well-established the tubes were omitted, and treatment with peroxide carbolic and with sublimate fomentations was begun. On the tenth day the purulent discharge had ceased; on the fourteenth the three lower sutures were removed from an apparently united aseptic wound. The hepatic segment was gradually closing with bright red granulations but the wound was not as yet suitable (too oval) for closure by waiting sutures On the thirty-second day after operation the silkworm-gut sutures were still in perfectly aseptic condition and after so long an exposure were still placidly waiting to be tied.

A CASE OF
IODISM IN WHICH ŒDEMA GLOTTIDIS NECESSITATED TRACHEOTOMY.

By N. W. Snell, M.D., M.R.C.P. Lond.,
and
L. H. Savin, M.B. Lond., F.R.C.S. Eng.,
ASSISTANT MEDICAL OFFICERS TO ST. MARYLEBONE HOSPITAL, LONDON.

Asphyxia from potassium iodide poisoning seems sufficiently rare to warrant the publication of a case.

M. R., a stout and lethargic widow aged 62, had suffered intermittently from varicose ulcers of both legs since 1913, and was admitted to St. Marylebone Hospital on August 28th, 1926 Her Wassermann reaction was negative, She had marked pyorrhœa alveolaris and was subject, in winter to exacerbations of chronic bronchitis; but she was otherwise a healthy woman. On Sept. 14th potassium iodide was exhibited.

That night, after 15 gr of the drug had been taken, she complained of discomfort and was examined upon the night round. She had swelling of both submaxillary glands, more marked on the right side. Next morning (Sept. 15th), after a total of 25 gr potassium iodide, she complained of a "cold." The submaxillary swellings were larger, the conjunctivæ suffused, and the pharyngeal mucous membrane was œdematous. The iodide was stopped (N. W. S.) and a tentative diagnosis of idiosyncrasy to iodides was made.

At 4 30 P M she was reported by the nurse in charge as "very dyspnœic with some obstruction to respiration" On examination (L H S) the throat was found to be more swollen, and a laryngoscopy showed œdema glottidis Breathing temporarily improved , but tracheotomy instruments were prepared, the position of the cricoid was marked, and 16,000 units of diphtheritic antitoxin were injected subcutaneously, the possibility of laryngeal diphtheria being in mind In fact, however, the swab then sent for examination was negative

At 8 P M on the same day severe dyspnœa recurred and a rapid tracheotomy had to be performed (L H S) with the patient in extremis and unconscious By this time the neck was so swollen that an ordinary silver tracheotomy tube was not long enough, and the wound had to be held open by the thumbs while the patient recovered breathing Eventually a longer rubber tracheotomy tube was inserted

In three days all the swelling had subsided The tracheotomy wound rapidly healed and the patient was discharged a fit woman on Sept 22nd, the ulcerated legs also having healed We now feel a certain trepidation when prescribing potassium iodide

A classical description of similar symptoms was that of H Huchard and P le Gendre[1] in their paper, "Crise laryngee (Œdème arytenoidien avec spasme glottique) provoquee chez un tabetique par l'emploi de l'iodure de potassium et ayant necessité la tracheotomie "

We wish to thank Mr Basil Hood, our medical superintendent, for permission to publish this case

Medical Societies.

BRITISH MEDICAL ASSOCIATION CONFERENCE.

A CONFERENCE was held in the Council Room of the British Medical Association House on Monday, April 4th, to discuss

Research and Animal Experimentation

Mr R G **Hogarth**, President of the Association, took the chair and the following motions were discussed by representatives of medical and scientific bodies present —

(1) That this Conference, believing that any withdrawal or curtailment of the powers at present granted under license and inspection, will hinder medical research to the detriment of the health and well-being of the community, wishes to enter a strong protest against any Bill which has for its object further restrictions upon experimental work on dogs or other animals

(2) That this Conference is of opinion that the existing law should be altered so as to permit, under proper provision for the prevention of pain and for efficient inspection and control, the use, for purposes of research, of some of the numerous stray and unowned dogs now taken up by the police and condemned to the lethal chamber, thus ensuring conditions which are essential to progress in physiological knowledge and to the application of this knowledge to the practice of medicine

(3) That *copies of the above resolutions* should be sent to the Prime Minister and to the Home Secretary, together with a note of the names of those present at the Conference and of the bodies they severally represent

The **Chairman** opened the proceedings by reminding the delegates that the agitation which they had met together to combat was not new, but was kept alive year by year by bequests to various societies for the special protection of dogs It was not distinguished by any scrupulous accuracy, and he doubted whether five per cent of those who conducted its emotional propaganda were aware of the rigid restrictions under which animal experimentation was carried on, or of the beneficial results which had accrued from it He did not challenge their sympathy for the sufferings of animals, but their inability to appreciate the deeper issues involved The overwhelming weight of scientific opinion laid stress on the unique experimental value of the dog because of the similarity of its physiological processes to those of man He asked the meeting to say in effect to Parliament "Trust our scientists, and trust them fully" Less harm would come to dogs from them than from the short-sighted advocates of the Bill

The Threat to Research in General

Lord **Dawson** remarked that although the current agitation was ostensibly directed towards excluding dogs from experimentation, the principle of experiment as a whole was involved For his part he was delighted ; it was much better to face the question outright than to allow their opponents to attack it in detail If it were wrong to use dogs it was wrong to use other animals It was unlikely that doctors who were trained to care for human suffering would be drawn into cruel and inconsiderate methods It could therefore be assumed that there was no cruelty of intention The fundamental point at issue was whether men were ethically justified in using animals for any of their own purposes , no one could pretend that the preparation of the turkey for the anti-vivisectionists' Christmas table was a pleasant process, or that horses really liked drawing heavy loads, or that cattle enjoyed being castrated Surely the answer was that special use of animals was justified provided that the end in view was sufficiently beneficial to mankind and that the animal suffered no undue discomfort It was often forgotten that animals had none of the terrors of anticipation and other mental agitations that often far outweighed human physical suffering The medical profession, with full sense of responsibility, assured the public that without experimentation it could not carry on If the public said that experimentation was not justified, well and good , he would like to see the question brought to a head If they took that responsibility, all the implications that followed were theirs He was satisfied that once the public understood what those implications were, it would not be long before they withdrew their support from the opponents of experimentation Was the public willing to take the responsibility of saying that the use of insulin was not justifiable , if so, the medical profession would like it stated in plain language. It must be understood that the work of research into the causes and treatment of such conditions as jaundice, gall-stones, typhoid, and lock-jaw, and into the action of such drugs as pituitary extract must cease if such a Bill became law Were the actions of new drugs to be tested on the wives and daughters of the public, he asked, or were no new drugs whatever to be used ? A dog was never used without good reason, but whether a dog was necessary or not could be settled by nobody but the experts concerned The profession appealed confidently to the public on the question as a whole, not on this mere subterfuge, and asked that their colleagues in research should be left undisturbed by this mischievous and harrassing interference

Dogs and the Surgeon

Sir **Holburt Waring** related his experiences in research work and in the use of animals, as an alternative to patients, for acquiring surgical technique. From a technical point of view a large dog was far and away the best If the public desired that progress should be made by surgeons, animals must be used, and in his opinion the amount of suffering thus entailed was much less than in experimenting upon patients He considered that surgeons, as a body, had a right to be allowed to try to make advances in their own sphere He had had personal experience of the effectiveness with which the legal restrictions on experimentation were enforced

Dr. G M **Robertson** spoke of the amount of suffering, of mind as well as body, that had been saved to the human race by the sacrifice, small in proportion, of a few dogs He quoted illustrative expressions of opinion from those people who, contrary to most normal men and women, regarded a dog as of greater value than a human being, and asked if legislation on so important a subject was to conform to the ideas of such people To those who knew the facts it was inconceivable that anyone could approve of the Bill, which was based on a failure of imagination. He then spoke of the importance of experimentation on dogs and cats to cerebral pathology, and quoted from O. Henry: "I am a Kentuckian and I have seen a great deal of both men and animals, and I never yet saw a man who was over-fond of horses and dogs but what was cruel to women" The public entrusted their lives to the profession, and it did not seem too much to expect that they would not cause unnecessary suffering to another of God's creatures

---

[1] Bull et Mém de la Soc Méd des Hôp de Paris, 1885

Mischievous Methods of Attack

Sir Thomas Lewis said that the science and practice of medicine had been built upon the examination of living people, the dissection of dead bodies, and experiments on living animals, and all our knowledge of human disease was derived from these sources Had any one of them been closed, medicine would have failed to emerge from the Dark Ages. He suggested that any one of his hearers should sit down and write a reasoned statement on the process and control of the circulation, or of the nervous system, without using any fact or inference derived from experiments on living animals Only then would he fully understand the fundamental part these experiments had played He illustrated this point from the cardiovascular system The supporters of the Bill displayed astonishing ignorance of the conditions under which animal experimentation was carried on. No dog could be kept in serious pain without the fact becoming immediately known, and there was no licensed building in the land in which such conduct would be tolerated. The recent petition of the National Canine Defence League proved by its inaccurate statements that its signatories were the victims of a mischievous campaign and unfitted to influence the decisions of Parliament. The leaders of the antivivisectionists in this country were unscrupulous or culpably negligent in presenting grossly inaccurate evidence and in perverting the meaning of plain words The campaign satisfied a morbid craving for the horrible and gruesome and the "tortures" of animals which brought to many right-minded people much needless suffering existed only in the imagination. Those engaged in attacking animal experiment were engaged in an attack on the progress of medicine, those who lent their support were upholding a campaign against the cure and alleviation of human suffering.

Lieut Colonel J. W. Brittlebank said that as a veterinarian he saw a good deal of the societies responsible for this emotional propaganda, and were it merely emotional, and not unprincipled, would not object to it, but actually there were no lengths to which these propagandists would not go He thought there could be no other civilised land where men who devoted themselves to the mitigation of suffering in man and animals were so pilloried as in this country He was there to offer the utmost support of the veterinary surgeons He emphasised the difference between the mental attitude of man and animals, and referred to the research on distemper, asking whether that was to be stopped.

The General Practitioner.

Dr H B Brackenbury said that an accusation of cruelty or callousness, or even of a lack of sympathy, was one which, if closely examined by any responsible person in the country, would be at once repudiated General practitioners associated themselves with those who knew a great deal more than they did about the actual experiments and recognised their value in everyday practice He mentioned particularly the testing of drugs and the treatment of cardiovascular and digestive disorders He failed to see how anyone could consistently support this Bill unless prepared to refuse the chief medical aids which his doctor could give him Much was heard nowadays of the importance of research work by general practitioners but this research could not begin on human beings: it must receive its impetus from animal experiments If the medical profession were going to create such a public opinion as would prevent the annual recurrence of such absurdities as this Bill, it was the general practitioners who must play the greatest part. This was no easy task, and it required a good deal of courage for doctors to tackle their patients on the question He was certain, however, that there was a very large body of people sincerely anxious for and willing to accept guidance, and he urged practitioners to throw themselves into the campaign, and to make opportunities where none were offered.

General Discussion

Lord Lamington (Research Defence Society) spoke of the persistence of certain highly-placed supporters of the Bill and the necessity for energetic countermeasures

Mr. E W Moss Blundell (*Field* Distemper Fund) pointed out that the work on distemper was for dogs but would probably lead to the relief of human diseases. The work was progressing admirably and receiving enthusiastic support from all over the world Its stoppage by legislation would be a calamity and a bitter disappointment to dog-lovers everywhere.

Lieut-Colonel F. E Fremantle said that the real difficulty to be countered was the feelings of dog-lovers who were blinded by their love, and were impervious to argument. A statement as to how much animals in general and dogs in particular had benefited by experiments would be very useful in dealing with these people.

Prof F. T. G Hobday described his experiments on the use of chloroform for veterinary operations and related the horrors of the pre-anæsthetic days. For these experiments he had had to obtain the most "brutal" licence and was now branded as a vivisector, but truth must prevail

LIVERPOOL MEDICAL INSTITUTION.

A meeting of this Institution was held on March 17th, when Dr. R. W. MacKenna read a paper on

Psoriasis.

It was a reproach to the profession, he said, that though psoriasis was one of the most ancient of recognised diseases, there was as yet no certain means of curing it Its cause was still unknown, though undoubtedly a definite familial tendency was traceable in about 30 per cent of cases The determining cause of the first outbreak was usually some slight trauma, but once a person had had an attack he was likely to suffer from recurrences all his life. The psoriasis papule, the initial lesion, was a characteristic pathological entity, and it should be possible to diagnose the disease from a single papule The appearances produced by systematic curetting (grattage) were very characteristic, and Dr MacKenna demonstrated by photographs of sections the anatomical conditions on which they depended He also gave an account of experimental observations, made with the help of Dr Elizabeth Hunt, in his clinic at the Royal Infirmary. No new and certain method of curing the disease had, however, been discovered

Dr R. E Roberts and Mr. St George Wilson contributed a note dealing with

The Treatment of Menorrhagia by X Rays.

Thirty-four cases had been treated, and it had been found that the technique adopted should vary according to the patient's age. In older women the object was to bring about an artificial menopause. whilst in younger ones—those under the age of 40—the aim was to avoid, if possible, any interference with fertility except as a last resort A dose that would cause sterility in a patient over 40 years of age would not have the same effect in a younger woman, which meant that there was a bigger margin for submaximal dosage in younger subjects If, however, it was finally decided to sterilise such patients it would take longer to bring about the desired result In older women a permanent amenorrhœa had been in every case successfully produced by X rays. In the younger group an amelioration of symptoms was brought about in most of the cases by submaximal dosage, and it was rarely necessary to proceed to complete sterilisation Most of the cases had been treated unsuccessfully by other means before X rays had been tried Dr Roberts and Mr Wilson also referred to irradiation of the spleen as an adjunct to the treatment of excessive bleeding, and to irradiation of the ovaries by very small stimulating doses in the treatment of primary amenorrhœa Too few cases of amenorrhœa had been treated in this way to allow of any conclusions about its value

Reviews and Notices of Books.

LISTER AS I KNEW HIM.

By JOHN RUDD LEESON M D , C M London
Baillière, Tindall and Cox 1927 Pp 212
8s 6d

THE work of great minds endures long after the earthly temples of the body have dissolved in dust, of that work later generations will have cognisance but the personal characteristics and mode of life of the worker will often be hidden, although of absorbing interest to those who have not had the opportunity or the privilege of personal relations with him alive Lister's labours by which he converted operative surgery from what was—before his teaching began to take effect—in many cases, and necessarily, a death-dealing art, to one which is in verity a life-giving one, are known to all men to the public now as well as to our profession, but the personality of the man himself as he appeared to his contemporaries and to those who had the honour of working with him is still largely concealed despite Sir Rickman Godlee's biography and the published estimates of a group of early and devoted followers Hence the appearance of Dr Leeson's book in this centenary year of Lister's birth is timely

The book is very simply written by a faithful disciple who had and has as any disciple of Lister must have, a whole-hearted reverence and love for his teacher Dr Leeson commenced medical study at St Thomas's Hospital which was removed from the Borough to its present site near Westminster Bridge in October, 1871 The site was new, as airy a one as could be found, and there was as much chance of sunlight as is possible in London, the building was new, the fittings were new, and the nurses were of the new school of Florence Nightingale Never did an institution start less weighed down by evil heritage Sir John Simon, who had been assistant surgeon at King's College Hospital (where Lister was afterwards to preach to audiences mostly apathetic), was one of the surgeons, and was also the first medical officer of health for the City of London and medical officer under the Public Health Act Everything to all appearance that could make for the successful healing of wounds was present at St Thomas's Hospital by Westminster Bridge “And yet” Dr Leeson says, “as far as surgery was concerned pyæmia, septicæmia, and erysipelas were as rife as ever” And the student of those days knew very much about the working of the wards, though the medical curriculum occupied only two and a half years when Dr Leeson joined his medical school, of which term the first year was taken up also with dissecting and attending lectures The spare time was devoted to walking the hospital Leeson on arriving at the latter portion of this time, which to-day, seems so terribly inadequate, asked one of the staff, the great Charles Murchison, how he had best spend this eighteen months and Murchison then gave this remarkable answer ‘If I were you, Mr Leeson I should not spend the whole of my time at St Thomas's, I should go to Edinburgh and follow the practice of Professor Lister, I believe there is a great future before his work and that it is well worth your while to study it” And it may be noted that shortly before this advice was given a series of papers was running in THE LANCET by Murchison, in juxtaposition to Lister's earliest reports of his results

Accordingly, armed with letters of introduction from Murchison to Lister and Grainger Stewart, the young student arrived in Edinburgh in the summer of 1873 and was admitted to Lister's wards. They were dark, gloomy, and sunless, but the patients were cheery and comfortable, there was little pus, no pyæmia and no putrid wounds, and there was—Mr Lister Consider what an impression the place, the work, the results of the work, and the personality of him to whom these results were due must have made upon a young and receptive mind fresh from the horrors of the ordinary surgery of those days Dr Leeson manages to make us realise something of his feelings He became dresser, then surgical clerk, and he describes with vivid touches Lister and his methods, his passion for accuracy and attention to detail, his never-ceasing personal interest in each patient, his kindliness, his courtesy, his modesty, as when he would say, “Never be afraid of confessing your mistakes, it is cowardly not to do so, and it may prevent others from falling into like error” In 1877, when Lister migrated to London as professor of surgery at King's College in succession to Sir William Ferguson, he offered to take his old clerk with him, but circumstances forbade the acceptance of the offer Besides the personal recollections of Lister, Dr Leeson supplies an excellent résumé of the history of antiseptics, the development of antiseptic dressings, and a description of an operation by Lister in the early days of the system when the spray was still in use

The book is well done Not only all medical men of the younger generation should read it but lay folk as well

DIABETES MELLITUS

The Pathology and Treatment of Diabetes Mellitus.
Second edition By GEORGE GRAHAM, M D ,
F R C P , Assistant Physician, St Bartholomew's
Hospital London Humphrey Milford Oxford
Medical Publications 1926 Pp 230 8s 6d

THE appearance of the second edition of this work will be welcomed by research workers and practitioners alike It is not only a concise enunciation of the present state of knowledge of carbohydrate metabolism, but this edition also contains practical information, invaluable to those who watch over the progress of diabetics in their daily lives, in a newly added chapter entitled Details of Treatment with Insulin The first three chapters of the book, which deal with the distribution, storage and physiological regulation of sugar in the body, have been brought up to date, it is important to note that insulin is only one, though the most important, of the substances produced in the body contributing to the regulation of the blood-sugar, the part played by adrenalin, thyroxin, and pituitrin is probably considerable A new chapter follows in which the history of the discovery of insulin is summarised and its properties and mode of action are set out, as far as they are at present understood So far as the muscles are concerned, insulin, it is suggested, converts glucose into a new kind of glucose (neo-glucose) but stores the dextrose as glycogen, while the glycogen in the liver bears no direct relation to insulin

With regard to treatment, Dr Graham is strongly in favour of the ladder diet as opposed to the maintenance diet extensively used in the U S A and Canada, which is, however, detailed in a special appendix His reasons for this preference are (1) the more rapid relief of symptoms, (2) the possibility of forming, under conditions of temporary fasting, a more accurate estimate of the severity of an attack, and (3) the valuable psychological effect on the patient who learns early to understand the principles of the treatment of his complaint The sense of well-being in patients treated with insulin is emphasised as more than compensating for the minor inconvenience of a daily injection Most diabetic patients below the age of 40 require insulin, and Dr Graham finds that patients between the ages of 40 and 60 are able to lead more active lives on a small daily injection For young children he finds that a standard of from 2 to 4 g of protein per kilo is necessary to maintain growth and development, and if this ration cannot be taken without the help of insulin the drug must be given Symptoms of over-dosage of insulin are well described and their treatment by sugar, adrenalin and pituitrin is set forth Finally, methods of effecting exchanges in the diet, which otherwise tends to become too monotonous, are detailed, a special appendix on food values being included at the end of the book Diabetic foods are prohibited unless their percentage composition of fat, carbohydrate, and protein is clearly stated In the last chapter the causation and treatment of diabetic coma are dealt with Dr Graham considers it safer to give 2 oz of dextrose together with the insulin to ensure a sufficiency of sugar in the body

The book is an admirable summary of the theory and practice of the most modern methods of treating diabetics.

CLINICAL PEDIATRICS.

By JOHN LOVETT MORSE A.M M D Professor of Pediatrics, Emeritus, Harvard Medical School London and Philadelphia · W B Saunders Co 1926 Pp 848. 42s.

Prof Morse states in the preface to this book that, while he hopes that it may be interesting to students and practitioners it was written primarily for his own amusement The author finds much to entertain him in many of the current methods of treatment and the theories on which they depend, and he brings to bear upon them a wealth of shrewd criticism and no little humour. He holds strong opinions and presents them dogmatically, which the student will appreciate One of the most interesting and original parts of the book is that devoted to dyspepsias and alimentary toxæmias, the account given both of the significance of symptoms and of the indications of treatment will be really helpful to the practitioner Prof Morse is insistent in warning the reader against the common tendency to assume that acidosis is the cause of all conditions associated with acetonuria Short, readable accounts are given of the fevers, and there is an admirable chapter on tuberculosis The chapters on infant feeding will disappoint those who desire to simplify the subject since the use of somewhat complicated milk formulæ for individual infants is expressly advocated In view of the great experience of the author and the attractive style in which the work is written it is likely to find a place among standard text-books on the subject

PSYCHO-ANALYSIS

Further Contributions to the Theory and Technique of Psycho-analysis By SANDOR FERENCZI M D. Compiled by JOHN RICKMAN M.A M D Authorised translation from the German by JANE ISABEL SUTTIE M.A., M B., Ch B, and others London Hogarth Press 1927 Pp 473 28s

THE bibliography of Dr Ferenczi s writings printed as an appendix to this volume shows the gradual transference of his interest from organic neurology to psycho-analysis which he has practised for eighteen years; since he holds a prominent position among psycho-analysts this collection of papers may be taken to represent authoritative views Most of them are written for those engaged in the speciality, and the section on technique discusses methods of "active therapy" designed to stimulate patients in whom free association has reached a dead end These consist chiefly of depriving the patient of some pleasurable activity the most striking being the setting of a limit to the analysis and they seem to have roused the opposition of his more conservative colleagues Apart from this internal controversy a few polemical essays are to be found in the section on nosology Analytical findings are given in two cases showing hysterical anæsthesia in one the loss of sensation being connected with the memory of a trauma whilst in the other, it is a true stigma representing unconscious phantasies. We may accept these statements and yet question the entire repudiation of Babinski's explanation that hysterical anæsthesia is suggested by the doctor This explanation was the result of clinical experiments that have been confirmed by other observers and Ferenczi s dismissal of it is as unsatisfying as Babinski's theory that hysteria is nothing but suggestion The chapters on the general theory of the neuroses are suitable for the ordinary medical reader, but some of the later portions will be unintelligible to him Dr Rickman in an introductory note praises the imaginative quality of the author, and compares the understanding of psycho-analytical literature with that of mathematical science; according to him understanding in each case is a matter of unconscious mental adjustments, the adjustment in mathematical science being almost entirely intellectual and in psycho-analysis almost entirely emotional. The acceptance or rejection of psycho-analytical observations is often emotionally determined, but some chapters in this book—that, for example, on the acceptance of unpleasant ideas—demand serious intellectual effort There seems no link between the theories enunciated in that chapter and whatever material they are presumably based upon Easier and of more practical use are the chapters on medical jurisprudence and criminology, though either emotion or intellect urges the rejection of the view that the Œdipus myth found alike in savage totemism and the unconscious of the civilised, represents an actual tragedy in the history of mankind. The book is decidedly uneven but will be welcome to those who wish to enlarge a previous knowledge of the subject

The Ego and the Id. By SIGM. FREUD, M D, LL D Authorised translation by JOAN RIVIERE London Hogarth Press 1927 Pp 88. 6s

THERE have been many systems of psychology which sum up if they do not explain, general principles of human behaviour Freud having explored the repressed material of the unconscious, here attempts to set up his own system covering mental activity in general Nietzche used the term *das Es* (the id) for whatever in our nature is impersonal; Groddeck, following him used it for the unknown and uncontrollable forces by which we are "lived"; Freud looks upon the mind of the individual as an unknown and unconscious id upon whose surface rests the ego, developed from it by the direct influence of the external world But there are qualities in human nature—the higher, moral or spiritual qualities—which as Freud says, psycho-analysis has been reproached for ignoring These he ascribes to an ego-ideal or super-ego, formed during the phase when the Œdipus complex is mastered and permanent expression is given to the influence of the parents: the parents are perceived as the obstacle to the realisation of the same Œdipus wishes and the child's ego erects the same obstacle within itself, thus establishing the domination of the super-ego in the form of conscience or the categorical imperative Since the ideal is set up in opposition to the unconscious instinctual trends its connexion with them leads to the super-ego itself being to a great extent unconscious and inaccessible to the ego.

From the psycho-analytical point of view these differentiations within the mind are supported by clinical findings and are indeed, formulated as a working hypothesis to explain them Further considerations involving the supposition of a death instinct are frankly more speculative and decidedly more obscure On page 55 we read that the self-preservative instinct must be assigned to the ego and the effort to understand how an instinct can belong to a part of the mind that has developed as a perceptual system is only one among many demanded One finishes the book with the regret that orthodox psychologists are still too remote from psycho-analysis to help it with effective and useful criticism Some of the basic problems of psychology are here considered and it should be possible to find a relation between the Freudian point of view and that of other workers.

PRACTICAL NURSING

For Male Nurses in the R A M C and other Forces Second edition By E M and A R Hassard London John Bale, Sons and Danielsson, Ltd 1927 Pp 407 4s 6*d*

The second edition of this excellent book has been brought up to date by various notes on modern methods such as insulin, and by a chapter on radiant heat, electricity, and massage, contributed by Miss Shinkwin We can find no reference either in the index or the text to the technique of giving of salines or of fixing the patient in Fowler's position. Those practical details which are included are given clearly and fully, and the commonest error of text-books on nursing is avoided—namely, that of giving enough detail to obscure the principles, yet not enough to enable the reader to carry out the procedure in practice The military pattern of handbook exemplified in manuals on drill and ceremonial is well adapted for the purpose of giving exact directions The arrangement of the subject matter seems unmethodical, but, on the whole, the ground is well covered and the book should have a much wider appeal than to those indicated in the title

CAVERNOUS SINUS THROMBOPHLEBITIS.

By Wells P Eagleton, M D, Medical Director, Newark Eye and Ear Infirmary New York The Macmillan Company 1927 Pp 196 20*s*

This monograph deals with a grave condition The author states that of 25 cases under his observation only four recovered He divides the cases into groups by distinguishing the source from which the infection reached the sinus, justifying a somewhat elaborate classification by variations in the operative technique which the different cases require The operative methods he suggests are certainly courageous, consisting in preliminary ligation of the common carotid followed by drainage of the cavernous sinus by a route which depends on the source of infection That he should have succeeded in saving four patients in this desperate condition is a strong recommendation for the methods he adopts The actual cases are described in the utmost detail so that the reader is able to form his own conclusions as to the treatment adopted in each The volume furnishes in a convenient form all the information at present available on a dangerous complication which is fortunately rare

READABLE PHYSIOLOGY AND HYGIENE

By J Argyll Campbell, M D, D Sc, Member of the Research Staff, National Institute for Medical Research, Hampstead London G. Bell and Sons, Ltd, 1927 Pp 229 3*s* 6*d*

This book, intended for beginners, is the latest addition to "Bell's Natural Science Series" It is, indeed, a readable little volume, and well illustrated The book is up to date in several respects; not only does insulin find a place, but the distinction between vitamins A and D is explained, and an account is given of "oxygen debt" The smoke nuisance is discussed and the danger of odours to health, a popular scare, is satisfactorily disposed of But the author does not seem to have realised that a modern text-book, even for young children, must deal with all the systems of the body There is no satisfactory account of the kidneys, nor indeed of the excretory channels at all and the physiology of sex is ignored except for a short paragraph (p 23) on the growth of the ovum The kidneys and generative organs are mentioned in a table on p 14, but the child's curiosity having been aroused Dr Campbell fails to satisfy it Perhaps in a future edition these omissions will be rectified, for the attention given to the historical aspect of physiology makes this book a better introduction to the subject than some others which give the false idea that all has long been known about the functions of the human body

Reports and Analytical Records.

SISTOMENSIN

(Clayton Aniline Co, Ltd, Upper Thames street, E C 4)

Since the publication of a leading article on March 12th we have received from the Clayton Aniline Company samples of Sistomensin, an ovarian extract prepared under E P. 113,311. We arranged for biological tests of these samples and the results are detailed below We have, therefore, pleasure in withdrawing the statement that none of the commercial material which has reached this country appears to fulfil the biological test of producing œstrus when injected subcutaneously into a female rat We regret that an incorrect impression of the potency of Sistomensin should have been conveyed

STOCK'S MEDICINAL BRANDY (THREE STAR).

Camiss and Stock, Distillery, Barcola

Wholesalers, Distributors for the United Kingdom, and Exporters V Canova and Co, 20, Piccadilly, London, W 1

On analysis this brandy gave the following results —

Alcohol, by volume	40 0	per cent.
Proof spirit	70 0	" "
Alcohol under proof	30 0	" "
Extractives	0 85	" "
" containing sugar	0 75	" "

Secondary products expressed as parts per 100,000 of absolute alcohol present —

Acidity (acetic acid)	60
Aldehydes	31
Furfural	3
Esters as ethyl acetate	176
Higher alcohols	130

A consideration of these secondary products indicates that the brandy is pure and that it has not been blended with neutral spirit The palate is mellow and agreeable, and the brandy is obviously suitable for medicinal purposes

Growth of the Royal Northern Hospital —At the annual Court of Governors it was reported that, at 4965 last year, the number of out-patients had more than doubled since 1914 There are now 400 beds and the maternity department has double the applicants for beds that can be accommodated The X ray department is being rebuilt and last year more than 12,000 light treatments were given. The income has increased from £24,000 in 1913 to £81,000 last year The average cost of each patient in 1926 was £3 15*s* 6¼*d*, and a small fractional reduction in the average cost of each of 241,000 out-patient attendances has saved £900 The year's work left a deficit of £7780, which was more than accounted for by a decrease in legacies

PRISONS AND PRISONERS[1]

THE latest official report on British prisons is distinctly reassuring, for it everywhere reveals dissatisfaction with the present system and a determination to see it improved Prison reform depends so much on national sentiment and arouses such formidable opposition, that progress must necessarily be slow, but each step forward represents a real moral gain. One hopeful sign of advance is the decrease in receptions, in 1925–26 they were 882 less than in the previous year, and those in turn were 2597 less than in the year before Even more striking is the contrast between recent times and those before the late war, for whereas in the first five years of King Edward's reign the average yearly convictions per 100,000 population were 512, those for 1925–26 were only 110 The chief factors in this decline have been probation, allowance of time in which to pay fines, the working of the Mental Deficiency Act The activities of the various prisoners' aid organisations, and the training given during imprisonment have also contributed Much, nevertheless, remains to be done, and however gallantly voluntary workers may strive to make up for deficiencies in legislation, no further great advance will be made until these deficiencies are remedied One of the outstanding causes of failure in the present system, perhaps, is the infliction of short sentences The prospect of prison is a strong deterrent to those who have never been there, but to make sentences short is to take away much of their prophylactic effect upon others Moreover, no system of prison training can work smoothly if many of those subject to it are only kept for a few days, and can therefore be taught nothing but the simplest work. Alternatives, however, are difficult to suggest; one possible line of improvement is by developing the probation system, but this is itself open to abuse, and leaves a great deal to the discretion of the police.

The second grave deficiency in the system is the detention of many mentally defective or disordered persons, for whom prison is an unsuitable environment It is the practice of some judges and magistrates, in dealing with offenders whose mental soundness is doubtful, to pass sentence without asking for a medical report or before a report has been obtained It is so easy for a court to obtain a report on the state of a prisoner's mind, and meanwhile to hold him on demand, that little can be said in defence of this practice. Fortunately it is not very common, but even if it ceased altogether, a considerable number of mental defectives would still be put in prison, because of a clause in the Mental Deficiency Act that requires proof of the defect having existed "from an early age" This excludes for instance, the post-encephalitic delinquent The real problem is found in the borderline case of deficiency or insanity, in which law-breaking is due, not so much to a defective intelligence as to an emotional abnormality, and where the prisoner's mental abnormality is so elusive as to put him out of reach of certification under the existing Acts This type of prisoner cannot be sifted out of the present system by any measures except the enactment of a completely new standard of mental fitness, and the provision of institutions where he could be cared for, studied, and, as far as possible, improved If he could thus be eliminated, the prison system would be freed from one of the chief obstacles in the way of its evolution into what the Report calls "a place for hard work, discipline, and education, with a view for rehabilitation on completion of the sentence"

[1] Report of the Commissioners of Prisons and the Directors of Convict Prisons for 1925–26 London H M Stationery Office. 1927 1s 6d

An International Penitentiary Congress was held in London in 1925, and its resolutions showed full recognition of the need for this reform Before, however, any scheme can be drafted for discussion by Parliament, it is necessary to know two things One is the standard by which the medical officers of prisons would decide what prisoners they would recommend for special treatment The second is the approximate number of prisoners for whom special accommodation would be necessary If these two points were determined with the authority of the Prison Commissioners, it should be possible for the Government to frame legislation providing for execution of the work by voluntary bodies under State direction and subsidy—an arrangement which works, passably well, at any rate, in many other departments of social welfare The evidence in favour of the principle is overwhelming, and, if a practical scheme could be put before Parliament, there is little doubt that it would become law

ENCEPHALITIS, HERPES, AND ALLIED DISEASES

In spite of the vast amount of experimental work undertaken in the past few years on the experimental transmission of encephalitis lethargica to animals, the precise nature of the ætiological agent is still unknown, and the question of definite experimental transmission remains unsettled Nor has the relationship between this disease and herpes been satisfactorily defined The evidence brought forward recently has done little to clarify the situation, but the facts are worth noting, if only to emphasise the difficulties of the problem Japanese workers have been concerned with the blood picture of the disease and with its histological characteristics The Tokyo Institute for Infectious Diseases includes in its Scientific Reports for 1925 two papers on the severe epidemic in Japan in the late summer of 1924, when over 6000 cases were officially reported with a 55 per cent mortality M Ono and S Kojima found a neutrophil leucocytosis in the first week, together with a reduction of lymphocytes and eosinophils During the second week the neutrophil leucocytes decreased in number, to be followed in the third week by a relative and absolute lymphocytosis The blood picture only returned to normal after several weeks M Nishibe contributes his views on the vexed question as to what histological appearances may be regarded as typical He inoculated 94 rabbits, mostly subdurally, with brain emulsion and cerebro-spinal fluid from human material Histological examinations of the brains of these rabbits showed round-cell infiltration of the meninges in 7 4 per cent and perivascular infiltration in 5 3 per cent Control uninoculated rabbits showed similar meningeal and perivascular infiltration in 9 1 and 13 6 per cent respectively, these lesions being due to spontaneous meningo-encephalitis in the rabbit The presence of these round-celled infiltrations is, therefore, not considered by this observer to be due to human encephalitis virus Nishibe holds that the essential lesions of experimental encephalitis are widespread and marked degeneration of ganglion cells with vacuolation, disappearance of Nissl's granules, neuronophagy, hyperæmia, and small hæmorrhages The changes occur chiefly in the thalamus and midbrain, but any portion of the central nervous system may show lesions Using these changes as a criterion of experimental epidemic encephalitis Nishibe concludes that the virus is pathogenic for rabbits, is filtrable and transmissible

Two French workers, J Dechaume and F Lebeuf (*C R Soc de Biol*, 1926, xcvi, 43), also describe the results of intracranial inoculation of young rabbits in the meningeal space with emulsion of cortex, midbrain, and spinal cord taken aseptically from a fatal case of encephalitis lethargica 36 hours after death After an incubation period of six days one animal showed some degree of rigidity of the limbs, torpor with intervals of jerking of the feet, and died 24 hours later Cultures from the brain of this rabbit were consistently negative, but histological examination showed *perivascular and meningeal infiltration* with lymphocytes, increase of neuroglia nuclei, and degeneration of nerve-cells, as evidenced by disappearance of Nissl's granules and vacuolation of nuclei A second rabbit was inoculated with brain emulsion from this animal, showed no symptoms, and was killed on the eighteenth day after inoculation A similar histological picture was observed A third rabbit inoculated with material from the second showed no symptoms within a month The authors claim to have transmitted encephalitis lethargica to the rabbit, and do not consider that the above findings are due to the spontaneous meningo-encephalitis of the rabbit The histological appearance of the brains of rabbits suffering from herpetic encephalitis is the subject of a recent paper by C Da Fano (whose premature death we recorded last month) and J R Perdrau According to these observers the changes are extensive meningeal perivascular and parenchymatous infiltration, atrophy of nerve-cells, and disintegration of nerve-tissue, true and pseudo-calcification, reactive changes such as new production of blood-vessels, proliferation of connective tissues, and hyperplasia of neuroglia cells The changes are totally different from those found in the spontaneous meningo-encephalitis of parasitic origin, and are considered to be specifically herpetic When fresh these brains are non-infective, but when preserved in glycerol the virus of herpes can again be recovered These lesions in rabbits resemble more closely the picture of encephalitis lethargica in man than the acute herpetic disease described by numerous authors

Levaditi's name is everywhere associated with a series of able researches on the question of the possible relations and differences between the varieties of herpes, and of the apparent connexions between the latter and other toxi-infective states of the encephalitis class He has recently set out his ideas in a fine monograph,[1] which deserves perusal from cover to cover, whether the reader agrees with the conclusions or not is in reality almost a secondary consideration, for he will learn much in studying Levaditi's scientific method and cautious deductions Briefly, the thesis set forth is to the effect that herpes and zona (herpes zoster) are clinically and ætiologically distinct on the one hand, on the other, they are equally infective and contagious, and the virus of each belongs to the neurotropic category The major part of the volume treats of the author's personal experimentation in support of these views, and is replete with well-systematised data, the cumulative effect of which on the reader's mind is impressive if not absolutely convincing Much care is devoted to the interesting theory that the

---

[1] L'herpès et le zona ectodermoses neurotropes By C Levaditi, Pasteur Institute, Paris Paris Masson et Cie 1926 Pp 388 5s

virus of herpes (*sensu strictiori*) is identical with that of epidemic encephalitis, though in this respect repetition of the experimental evidence seems called for, as we feel rather too much reliance is placed on an individual series of researches More speculative, perhaps, are the author's explanations of the way in which the virus passes from the skin by neural routes to the neuraxis, he coins the term "neuroprobasia" (neural advance, we might) say for this, imagining that the virus, once introduced in the protoneurone, proceeds forward by cultivating itself locally in successive neuronal segments and leaving behind it tissues self-vaccinated against it In the current issue of the *British Journal of Dermatology and Syphilis* J R PERDRAU reviews his own recent work on herpes and encephalitis, upholding LEVADITI's view of the identity of the viruses In the same journal A. C. ROXBURGH contributes an interesting article on the relations of the facialis, zoster, and genitalis varieties of herpes, particularly from the clinical aspect The relationship of herpes zoster and varicella is discussed, and the author thinks that a large number of cases of spontaneous zoster are due to the same virus as varicella, and cites a number of problems regarding the connexion between these two diseases. In another paper S. P. BEDSON shows that the fluid from certain human bullous lesions (other than herpes facialis and zoster) when inoculated intradermally into the plantar epidermis of the guinea-pig produced lesions characterised by vesicle formation and similar to those produced by herpes and foot-and-mouth disease The infective agent can be transmitted through a series of guinea-pigs and is immunologically different from febrile herpes The nature of the virus is as yet unknown, and these observations should stimulate further work on the subject German observers, E GILDEMEISTER and K. HERZBERG (*Deut Med Woch*, 1927, i, 138), have also studied the inter-relationship of variola, herpes, and foot-and-mouth disease, using the intracutaneous method of inoculation into the plantar epithelium of the guinea-pig Their experiments show that in guinea-pigs inoculated as above with herpes there is a partial immunity to variola. A similar immunity exists between variola-immunised animals and herpes This partial cross-immunity is definite and specific On the other hand, there is no immunological relationship between foot-and-mouth disease and herpes Whatever the difficulties of interpretation revealed by these results, the problem appears worthy of closer study than it has yet received

NEWCASTLE-UPON-TYNE MOTOR ACCIDENTS.—The 176th annual report of the Royal Victoria Infirmary, Newcastle-upon-Tyne, states that last year 986 persons were treated for accidents directly due to motor traffic, 432 of whom were retained as in-patients This is double the number of the previous year, with the consequence that one ward is occupied nearly all the year round with cases of this description, and that the waiting-list is greatly lengthened, the number on the list at the end of the year was 2100 The average stay of in-patients was 15 3 days Out-patient attendances increased by nearly 44,000 Expenditure exceeded income by £9835 The whole situation of the hospital's needs is under consideration.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION—The special courses in April will not start until the end of the month. The first will be a course in Medicine, Surgery and Gynæcology at the Royal Waterloo Hospital for Women and Children, beginning on April 25th, and lasting for three weeks (Fee £3 3*s*) On April 26th will be given the first of eight clinical demonstrations on Tropical Diseases, to be held at the London School of Hygiene and Tropical Medicine on Tuesdays and Thursdays at 2 0 P.M. for four consecutive weeks The more important tropical diseases will be illustrated as far possible by cases in the hospital, and the fee will be £2 2*s* Four lecture-demonstrations on Treatment by Electrotherapy will be given by Dr. C B Heald at the Royal Free Hospital, on Wednesdays at 5 15 P.M beginning on April 27th, the fee for the four demonstrations will be £1 1*s* Copies of all syllabuses, of the General Course programme, and of the *Post Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole Street, London, W 1

Annotations.

"Ne quid nimis."

MOTORISTS AND THIRD PARTY RISKS.

AN important decision of the law of motor-car insurance will interest the medical profession which, more than any other, is daily exposed to the risks of the road In June, 1925, a motorist who had been to a wedding and had had too much to drink collided with a motor-bicycle on which were two young Army officers One of the two was killed, the other was injured. The motorist was charged with the manslaughter of the one and with unlawfully wounding the other He was convicted of the manslaughter and was sentenced to 12 months' imprisonment, the charge of unlawful wounding was not proceeded with. In addition to these criminal proceedings there was a civil action in which the surviving subaltern recovered £1500 damages and costs; the defendant motorist incurred costs in defending himself in both these actions. The latter thus had a big bill to pay; but the motor-car in which he was driving at the time of the accident was the subject of an insurance policy, and he therefore claimed to be indemnified in respect of the accident. The insurance company repudiated liability on the ground that the motorist was committing criminal acts in that he was drunk and was driving to the danger of the public, thus he increased the risk borne by the company, and it was contrary to public policy that he should be indemnified against the consequences of his criminal acts

In a judgment which the insurance company will probably take to a higher court, Mr. Justice Roche held that the company must pay up on the policy because the motorist's criminal act was negligent and not deliberate If the motorist had too much to drink at the wedding, it was both foolish and wrong; his lordship was, however, not prepared to hold that the motorist deliberately put himself into a condition of drunkenness and in that condition drove the car, nor to hold that there was such a degree of criminality as made it contrary to public policy that he should recover on the indemnity. It was difficult to believe that this motorist was any worse morally than people who in their sober senses drive to the danger of the public Both are guilty of negligence for which they are liable in a criminal court, but in neither case is the injury intended If he had had to decide that this motorist could not recover on his insurance policy, it would have meant that nobody who was driving to the public danger could rely on his insurance. "Unless I am compelled by decided cases to hold otherwise, I think it would be altogether contrary to public policy to hold that a man could not cover by insurance his liability to third persons arising out of dangerous driving; it would be a serious thing if juries, magistrates, and judges had to know that, if a man were convicted of any offence. the injured party could not recover any effective damage."

The decision, like a previous decision to the same effect by the late Mr. Justice Bailhache, draws a distinction between a deliberately criminal act and one which, though unlawful, is not done in circumstances in which it is manifestly unlawful or in which the person who does it knows it to be unlawful. The motorist was criminally negligent but he did not deliberately kill the Army officer. If Mr. Justice Roche had decided otherwise, the decision would have extended beyond the confines of motor-car insurance, and would have made itself felt in workmen's compensation insurance and elsewhere—for instance, where a workman was injured by an accident caused by a breach of the Factory Acts. The law. however, may be affected presently by fresh legislation compelling all motorists to insure against third party risks

RECENT WORK ON CONVULSIONS

There is at present no general agreement as to the precise part of the brain in which convulsions arise. W. E. Dandy and R. Elman[1] recently found that after injury of the pre-Rolandic cortex in dogs or cats, by incision or by inclusion of a foreign body, convulsions occurred for a time spontaneously, and for several months they could be induced with one-third to one-seventh of the dose of absinthe required to produce convulsions in the normal animal. In these experiments, all unilateral, the pre-Rolandic cortex was never completely destroyed but was only injured. The conclusions drawn from these experiments were: (1) that injury of the pre-Rolandic cortex lowers the threshold for convulsions, (2) tentatively, that injury to other parts of the brain lowers the threshold to a less degree. In a subsequent series of experiments Dandy[2] has studied the effects of removal of the pre-Rolandic cortex. He found that clonic convulsions could be produced at will by direct stimulation of this area in a dog under light anæsthesia, there was an optimal intensity of stimulation, a stimulus too light or too heavy producing only a single jerk of the corresponding part of the body. Deep etherisation inhibited clonic convulsions entirely, with a less deep etherisation the movements remained localised, and when the ether was still further reduced they quickly became generalised. Stimulation of all other parts of the surface of the cerebral hemispheres failed to produce a motor response except when rather powerful stimuli were used on the cortex or subcortex contiguous to the Rolandic area, stimulation of the cerebellum produced contractions but never clonic convulsions. A tunnel was made through the cortex posterior to the Rolandic area and the subcortical motor tracts were exposed just above the internal capsule, stimulation of these fibres, the motor cortex being intact and uninjured, produced clonic convulsions, local and general, seemingly just as effectively as stimulation of the pre-Rolandic cortex. Stimulation of the subcortex aside from the motor tracts did not produce a response. If during a localised clonic convulsion the motor cortex of the contralateral side was excised by a sweep of the knife, the convulsion instantly and completely ceased; if during a generalised clonic convulsion the motor cortex of both hemispheres was excised by two rapid sweeps of the knife the convulsion instantly ceased in all parts of the body. When, after excision of the pre-Rolandic cortex on one side the subcortical motor fibres were stimulated, a convulsion did not ever again result on the contralateral side of the body, but clonic convulsions might appear on the same side (the opposite pre-Rolandic cortex being intact). After excision of the pre-Rolandic cortex of both cerebral hemispheres, clonic convulsions could not again be induced in any part of the body with stimuli of any intensity applied to the subcortical motor fibres. Excision of the cerebellum had no effect on any of these results, stimulation of the cerebellum with the pre-Rolandic cortex either intact or removed from one or both sides failed to produce clonic convulsions.

These experiments seem to show that the pre-Rolandic cortex is essential for the development of clonic convulsions. Whether any other parts of the cortex are also essential remains to be examined. The cerebellum is apparently not essential and appears not to influence the occurrence or nature of clonic convulsions, the influence of other large cerebral structures is less easily determined, and in these experiments no attempt was made to investigate it. The part played by the pre-Rolandic cortex in the production of the convulsion is evidently not merely the sending of stimuli down the motor tracts, since in the absence of this portion of the cortex the sending of stimuli down the motor tracts does not produce a convulsion.

THE STORY OF THE LUCIFER

Another centenary which occurs this week is that of the humble friction match, for it was on April 7th, 1827 that John Walker recorded the first sale of the newly invented "friction light" at a shilling per hundred, with twopence extra for the tin case. Walker was born in Stockton-on-Tees in 1781, and he died there in 1857. For the greater part of his life he owned a pharmacist's shop in his native town, but it appears that as a youth he was apprenticed to a Mr. Watson Alcock, a surgeon in the town. After completing his apprenticeship, he went to London, presumably to complete his studies, returning to become Mr. Alcock's assistant. However, Walker could not stand the horrors of surgical operations and he soon abandoned his original profession, and after a suitable training he established himself as a pharmacist. It is a curious coincidence that two days before the first recorded sale of "friction lights" took place there was born a man who was responsible for stripping surgical operations of that horror which drove John Walker from the practice of surgery to the chemical laboratory, where the familiar match was born. In his student days Walker had shown great interest in chemical experiments and these, no doubt, led eventually to his discovery of the "friction light" as he called it. For many years, however, he was said to have made his "invention" by a lucky accident. Since he did not divulge the exact chemical composition of his matches—for he steadfastly refused to patent what might have brought him a considerable fortune—spurious imitations were to be obtained in London by about 1830, and the invention of the friction match has consequently been attributed to various other people at different times. Prof. William A. Bone has had access, however, to an old Day Book of Walker's and in a recent article[1] he offers an explanation of how the discovery was made of what was undoubtedly the first friction match. It appears from records in Walker's own writing that for some years he had been making Chancel's "oxymuriate matches" for some of his customers. These consisted of strips of wood tipped with a mixture of potassium chlorate, sugar, and gum which were ignited by contact with strong sulphuric acid. As early as 1825, if not before, Walker was experimenting with the production of a "percussion powder" for use in sporting guns. This consisted of a mixture of equal parts of potassium chlorate and antimony sulphide, and it appears to have occurred to him to use a similar mixture for tipping the Chancel "dipping" match. Such "friction lights" were ignited by rubbing them on glass paper, a piece of which was supplied with each case. The first recorded credit sale was in 1827, as mentioned above, and by 1829 the fame of the "match," a term which Walker now used, had reached London, where Faraday is said to have exhibited some at a lecture. Except for the placing of a brass tablet on Walker's old shop in the High Street, Stockton-on-Tees, nothing has ever been done in this country to recognise or commemorate the discovery of what is now probably the most universal saver of time and trouble.

A NEW PARTIAL VACCINE AGAINST GONORRHŒA

The production of immunity to the gonococcus is not yet properly understood and is denied by some as a natural process in the cure of the disease. The discovery and trial of a new principle in the vaccine therapy of gonorrhœa is reported in a short preliminary paper in the *Journal of the Royal Army Medical Corps* for March 1927, by Major E. C. Lambkin, Major Lyn Dimond and Captain W. J. Robertson. The idea underlying their work was, they state, "to find a non-toxic gonococcal vaccine for use (*a*) intraurethrally as a local immunising agent as used by Besredka in other conditions, and (*b*) for general use to be applied intradermally, subcutaneously, intramuscularly, or intravenously" In order to achieve this the gonococcus was grown on special media washed off and fractionated. When the germ is grown on a medium rich in animal nucleo-protein one-third of the strains develop polar (Babes-Ernest) bodies composed of alpha-nucleo-protein and beta-nucleo-histone A 2 per cent salt solution, while dissolving the latter, is able to separate these polar bodies from the organisms and centrifuging allows the α-nucleo-protein to be separated from the β-nucleo-histone which is in solution by the saline Both bodies possess antigenic properties but the β-nucleo-histone is more potent than the other besides being relatively non-toxic and therefore especially suitable for vaccine use. For intradermal, subcutaneous, intramuscular, or intravenous injections a strength is used which is the product of 1000 million gonococci per c cm. in 2 per cent saline. 0 2 c cm. of this being injected every two days For intraurethral injection a standard solution in 2 per cent saline is made so that the nucleo-protein of 100,000 millions of organisms is contained in 15 c cm To this is added 1 per cent of sodium taurocholate, the reaction adjusted to a pH of 7·2, and brought up to 100 c cm. with mucin The urethra is irrigated with a 1 in 20,000 solution of potassium permanganate and a dose of 20 c cm of the vaccine preparation is then injected and retained for three or four hours This is repeated daily as long as gonococci are found in the discharge. As a test of cure endotoxin from strains not showing polar bodies is used The results satisfy the authors, but fuller reports will be awaited with interest The principle, it seems, is new and depends on the observation that the antigenic properties of the vaccine are confined to the polar bodies The authors regard the pH content of the urine as a factor of importance and it might be worth while to inquire what are the results of weak permanganate with an optimum pH of urine but without vaccine The difficulties of producing the vaccine in the quantities desired remain to be overcome but the principle, if substantiated, should be of wide application

WITCHCRAFT AND MEDICINE.

"Dress the wound with warm wine only, and lift no lancet against this young swordsman, for he was born under the Sign of Gemini, which is opposite in all things to the Sign of Sagittarius Therefore the sight of pointed weapons induces in him a kind of madness and he is very handy with a cutting edge himself" The speaker is an English man-at-arms who strides into a spirited mediæval romance by Mr Leslie Barringer[1] The mock-portentous conclusion to this piece of good advice reveals an age when common sense in treatment of wounds and injuries required metaphysical justification. Cupping and suppurative medicaments being thus discouraged, we are told that the hero's gashed thigh "had a better chance of healing than was given to many such wounds in those times" Mr Barringer has brought his casual use of medicine and surgery into apt line with his period The latter is apparently the middle of the fifteenth century; the scene of the story is an imaginary European kingdom with a Breton flavour about its coast-line. but a frontispiece map removes the Ruritanian difficulty usual in fiction of this kind The action is well-sustained, and the love-interest inevitable on popular grounds but the book is remarkable for its treatment of the theme of witchcraft The publisher's announcement promises "witches most foul," but the hero—a runaway and a minor when the main action opens—blunders into knowledge of the witches which sets the latter in at least as favourable a light as his relatives and peers amongst the almost sovereign barons of the country. Briefly witchcraft is here visualised not as a form of heresy but as a survival of heathendom—a debased Dianic cult driven into the hills and waste places, but deeply rooted in the peasantry (*pagani* indeed), and affording by its manifestation some relief from the appalling social weight at the base of the feudal pyramid We are reminded of the words of Michelet in *La Sorcière*: "the mediæval peasant would have burst, but for his hope in the Devil" No clear picture is shown of ritual or operative magic. but the suggestion seems to be that the power of the witches rested ultimately upon drugs Members of a coven are seen riding on horseback to their assembly; discovery of a secret stair dispels a suspicion of levitation. a too-confiding witch employs ventriloquism to re-establish awe in her companion. Naturalistic explanation is not however. overdone, and the darker features of the cult are not ignored Incidentally the one potion used to further the action is a pharmaceutical failure; an aphrodisiac is administered. but circumstances are unfavourable, and the end-result is homicide This is a good romance, which may be recommended not only to novel readers. but to students of that age when medicine and mysticism were inextricably mixed.

FORM AND FUNCTION

Parents, school-masters, and school-mistresses must often feel proud of the lusty young things which grow up nowadays under their guidance. The well-being of the baby is measured by the balance, which even in its most domestic form is, at any rate, a more objective criterion than nurse's prejudiced eulogy. In later years children are weighed and measured as they pass through their school terms, and finally there are produced the big. handsome, wholesome-looking young people of 20 and thereabouts who have become almost commonplace No one can doubt that there has been a general increase in size; school-boys of over 6 feet and weighing 12 stone or more seem quite common now, and the change in school-girls is perhaps even more striking A recent number of the *Journal of the American Medical Association* (March 19th, 1927, p 908) gives some data for American boys, showing that they are taller by fully 2 inches than were comparable boys 50 years ago Nor will anyone doubt that this change is due to hygienic betterment and especially to the more ample diet, caloric and vitaminic, to which so much attention is now paid The result is artistically beautiful and must be cheering to the dietitians But is it wholly for the good? Is there any evidence that larger people are even healthier than their more stunted companions? And in a field less open to quantitative measurement, is there any evidence that they will make better citizens—physically. mentally, and morally? The answers to these questions, if they can ever be had. must wait the experience of the future Meanwhile data are obtained which increase one's misgivings The experiments of Drs J E. Anderson and A. H Smith[1] have achieved some notoriety in the lay press They show that rats which are so underfed that they do not increase in weight can learn their way through a maze more quickly than normally fed and normally growing controls, and can relearn an old puzzle more quickly, too, after a period of abstention from experience of it When the stunted animals were fed up and reached the weight proper for their age they were no cleverer than their companions. Such results are much more than amusing, for they bring within the range of tolerably accurate experimentation that conflict between body and mind which has been perceived by many thoughtful people since man reached the stage of civilisation at which he could sometimes eat less than he could get A certain amount of restraint and parsimony are seldom out of place. It is possible that "this feeding business" is being overdone and that tissues which have grown rather less exuberantly may perform their offices more satisfactorily

CONTROL OF TUBERCULOSIS IN U S A

IN an address recently given to the New York Tuberculosis and Health Association Mr. Godias J. Drolet, statistician to the Association, provides some interesting statistics of tuberculosis in the United States From a table giving the numbers of cases of tuberculosis and of deaths from tuberculosis reported in 1924 in 23 States and 11 cities, it is evident that, as in most countries, case-notification is very incomplete, thus in the State of Washington the number of cases notified is practically the same as the number of deaths registered—viz, 2202 cases and 2183 deaths In Rhode Island the deaths were more numerous than the reported cases A useful table is that giving the populations, deaths from tuberculosis, and beds available for tuberculosis in each State. In the whole of the States there were, in 1924, 99,579 deaths from tuberculosis and 73,715 beds available Another table summarises the reported results of sanatorium treatment obtained in answer to a questionnaire Information concerning condition on discharge was obtained from institutions disposing of 31,581 beds, of these discharges, 20 per cent represented deaths, 23 per cent condition unimproved, 42 per cent condition quiescent or improved, 15 per cent disease arrested With regard to utilisation of facilities, 221 institutions with 38,726 beds reported on July 1st, 1926, that 32,529 patients were under treatment, a user of 84 per cent The range of weekly cost of maintenance is very wide, it varies in New York State from 10 to 39 dollars, in California from 15 to 41 dollars, in New Jersey from 10 to 28 dollars More than 40 per cent of all patients remain in a sanatorium or hospital less than three months, and only 10 per cent of those admitted were classified as in the incipient stage of the disease

NEW METHODS OF TREATING BOILS AND COLD ABSCESSES.

THERE has been a wide awakening of interest of late in what is called protein shock therapy, the mechanism of which is the stimulation of bodily resistance by means of an injection of foreign protein For some time it has been almost impossible to open a medical journal without finding some reference to the results obtainable in various local infective conditions by injecting milk, albumin, or a vaccine of some kind or other To the scientific mind there is something unsatisfactory about irritating the whole body with a foreign substance in the hope of securing reaction in one or two centres of infection but without knowing what is happening or why. Dr. Franz Kuhn's latest paper[1] on the treatment of boils deals with an injection process that acts directly on the focus of infection, and produces an immune reaction throughout the whole cellular structure of the inflamed tissue, the substance employed being the patient's own blood The cupping of boils is no new thing, but, according to Dr Kuhn, unless capillary hæmorrhage is produced throughout the whole of the inflamed tissue much of the healing power of the healthy blood is lost Bier's apparatus, he says, with a lift of at most 50–100 mm Hg, does not break the capillaries, it only draws into the boil what would filter through their walls Success has been claimed for the injection of the patient's blood around the boil with a needle, but at best the effect is momentary and, in most cases the operation, in Dr. Kuhn's opinion, is useless. His technique is described in an earlier number of the same journal.[2] He employs a vacuum powerful enough to induce extensive capillary hæmorrhage, followed by an energetic use of hot packs to promote hyperæmia, and he claims that some boils need only one application of this treatment

In the *Presse Médicale* for March 19th Prof. H L Rocher, of Bordeaux, claims excellent results, in cases of cold abscess where no fistula has developed, from lavage with water at 60° C (140° F). He recommends it chiefly for *abcès ganglionnaires*, and articular and bone abscesses, especially those which occur in Pott's disease and in coxalgia Moreover, when the epidermis is on the point of rupturing, this treatment will often prevent a break by thickening and toughening the remaining layers One of its principal advantages is the rapidity with which it takes effect The water is boiled for ten minutes and allowed to cool to 140° F., where it is maintained Hayem's serum may, it is suggested, advantageously be used instead of water The needle or trocar used must be large enough to allow of easy aspiration First of all the collection of pus is withdrawn and then the abscess cavity is well laved with the hot fluid The caseous detritus on the pyogenic membrane is speedily broken up and carried away through the syringe at each aspiration, and by the end of the lavage the membrane is generally bleeding If the evacuated fluid is pink only the process may be continued for another three to five minutes, but if it is red the operation should cease All water should be withdrawn and, if the puncture is so large as to cause anxiety lest a fistula develop, a small poultice should be applied for 48 hours Prof Rocher admits that the treatment is somewhat painful, but not beyond the endurance of the ordinary adolescent or adult, he does not mention what anæsthetic he uses for children The process has generally to be repeated a certain number of times before the abscess is entirely dry, but some collections, even large ones, disappear after one lavage The method, he claims, gives better results than the injection of modifying liquids, and its simplicity should appeal to the practitioner.

THE LATE DR. F. B POWER

Frederick Belding Power, Ph D., LL D, who died of heart failure on March 30th at Washington, U S A, at the age of 74 years, was an American by birth and upbringing, who spent the most fruitful period of his life in this country, where he was Director of the Wellcome Chemical Research Laboratories from their foundation in 1896 until 1914, when he returned to America to direct the Phytochemical Laboratory at Washington Born at Hudson, New York, Dr Power commenced his association with pharmacy at an early age He worked as a practical pharmacist in Chicago and Philadelphia, where he was associated with Edward Parrish, of "compound syrup of phosphates" fame He graduated in pharmacy at Philadelphia and again at Strasbourg, where he acted as assistant to Prof Flueckiger In 1881 he was called to the chair of analytical chemistry at the Philadelphia College of Pharmacy, and two years later he established the school of pharmacy at the University of Wisconsin In 1896, at the invitation of Mr Henry S Wellcome, his *old class-mate* at the Philadelphia College, Dr Power came to England to direct the new Wellcome Laboratories and became responsible for the 168 scientific papers issued from the Laboratories communicated to learned societies during his tenure of office One of his most important investigations was into the active constituents of chaulmoogra and hydnocarpus seeds in the modern treatment of leprosy. The value of his work was recognised in the conferment of numerous honours, in 1908 the University of Wisconsin granted him the honorary degree of Doctor of Laws, and in 1913 he was awarded the Hanbury Gold Medal He was Vice-President of the Society of Chemical Industry from 1904–06, served on the council and publications committee of this society, and was awarded the Ebert Prize on three occasions. After his return to America he served on the committee of the United States Pharmacopœia, and in 1920 was elected Vice-President of the United States Convention One of the last honours that was bestowed on him was his appointment as a member of the National Research Council on the Committee of Federal Relations His death removes a figure of international influence in pharmaceutical and phytochemical research

THE BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES

WE publish in another column an importantly-signed letter bringing before our readers the objects of the British Institute of Philosophical Studies, and indicating clearly how useful such studies might prove themselves to medical men both in general and special fields Lord Dawson and his co-signatories suggest that the modern developments of medical science bring with them difficulties to medical men because the range of exact knowledge and accomplishment is much enlarged, and evaluations have become in every medical direction more hard to make, and also because medicine is now taking its place in a marked manner in general matters, while society at large is an increasingly complicated affair The followers of medicine are therefore required to think logically, not only on questions concerning their own science or dealing with the administration of their own calling, but to think with equal insight and equal clearness upon the part that they should play as general citizens for the common good, particularly, as when happens so frequently, the medical side of the question is of the chief public importance The particular training of medicine provides both well and ill for the clear thinking that is necessary in all these situations Much of medicine must be in itself a profound philosophical study, but it may easily happen that what may appear to the followers of medicine as the logical view will be in apparent antagonism to what is called common sense—not necessarily good sense Now the Institute proposes to help its members to arrive at sound conclusions in these situations, which may present themselves either as the necessary accompaniment or complication of practice, or as problems in general sociology. As the letter to which we refer points out, the position must often arise when the medical practitioner feels the need of that comprehensiveness of vision which would come from taking counsel with those engaged on other pursuits The British Institute of Philosophical Studies proposes to afford opportunity for just such coöperation

LUMINOUS BACTERIA

THE phosphorescent bacteria which are common in many marine products have been well known for many years, a stale herring in a dark room will often give a remarkable demonstration. Why the bacteria should do it is even more a mystery than is the emission of similar light by the various higher animals which are capable of luminosity. Some years ago Prof E N. Harvey of Princeton University collected the available information in handy form[1] It now appears that the light-giving capacities of bacteria have been utilised in different ways by other organisms Some cuttle fish have a highly organised luminous organ furnished with a pigment layer at the back and a lens in front not unlike an eye; inside is a mass of glandular tissue from which the light proceeds and Pierantoni has claimed that the light actually comes from great numbers of bacteria which live symbiotically in the cells of the host His evidence is not altogether conclusive, but it is substantially in favour of his view More recently Yasaki has described[2] a curious case in Japan where certain fresh-water shrimps are infected with a vibrio-like organism and become in consequence brightly luminous In this instance the relation is one of infection rather than of symbiosis, for the bacilli are pathogenic and kill the shrimps within a few hours of their becoming luminous. Other species of shrimps may be infected experimentally.

A DEPARTMENT for the treatment of diseases of the skin has for many years been developing at the General Infirmary at Leeds When assistant physicians were first appointed in 1884, an arrangement was made whereby the skin cases were seen by one of the officers along with his other cases. Then, some 28 years ago, the increase of the work led to the skin cases being segregated and seen on a separate day, but still by one of the assistant physicians. Under this plan the number of patients increased, for, in some respects, it marked the existence of a special department and it was conducive to better teaching. When cases were admitted to the wards, however, they were placed under the care of the physician of the week. Acting under the advice of the honorary staff, the board of the infirmary have now decided to appoint a special honorary officer and to place him in charge of a reorganised department Here he will have excellent facilities for out-patient practice; ten beds will be allotted to his department at first, but there may well be a chance of further expansion

FROM Oct 1st the monetary value of all the Beit Memorial Fellowships for Medical Research will be increased The junior Fellowships will in future carry a grant of £400 a year instead of £350, whilst the fourth year Fellowships will be valued at £500 instead of £400, and the senior Fellowships at £700 instead of £600 The next election of junior Fellows will be held in July, and the Fellows then elected will be expected to begin work on Oct 1st The usual tenure of junior Fellowships is three years. Applications must be made before June 1st, and further information may be had from Sir James K. Fowler at 35, Clarges-street, London, W. 1.

IN view of a statement made in a leading article on March 12th, on the potency of ovarian extract now on the market, we would draw our readers' attention to our column on Analytical Records (p 764)

Summer Time will commence in Great Britain, Ireland, the Channel Islands, and the Isle of Man next Sunday morning, April 10th, at 2 A.M, when the hands of timepieces should be advanced one hour

TREATMENT OF THE FUNCTIONAL DYSPEPSIAS.

PURELY functional dyspepsia is probably less common than is supposed, and before treating a case as such it is well first to eliminate by thorough investigation all possibility of organic disease within the abdomen For this purpose a careful and detailed clinical history is more important than any other method of investigation If this shows that real *pain* (as opposed to mere discomfort) or vomiting or wasting has been a prominent symptom it is almost certain that organic disease is present, although the absence of these does not necessarily mean that the case is functional The organic conditions chiefly to be thought of are carcinoma, gastric or duodenal ulcer, gall-stones and chronic appendicitis Early carcinoma is, of all organic conditions, the most difficult to exclude. The most suspicious symptoms of it are loss of appetite and wasting, along with some gastric discomfort, and if these come on in a man of middle age who has previously had a good digestion, carcinoma should be thought of In ulcer cases pain is always present and is characteristically "punctual," appearing at a definite time after meals and, especially in duodenal cases, being temporarily relieved by the taking of more food In ulcer, too, the symptoms

NEW METHODS OF TREATING BOILS AND COLD ABSCESSES.

There has been a wide awakening of interest of late in what is called protein shock therapy, the mechanism of which is the stimulation of bodily resistance by means of an injection of foreign protein For some time it has been almost impossible to open a medical journal without finding some reference to the results obtainable in various local infective conditions by injecting milk, albumin, or a vaccine of some kind or other To the scientific mind there is something unsatisfactory about irritating the whole body with a foreign substance in the hope of securing reaction in one or two centres of infection but without knowing what is happening or why. Dr Franz Kuhn's latest paper[1] on the treatment of boils deals with an injection process that acts directly on the focus of infection, and produces an immune reaction throughout the whole cellular structure of the inflamed tissue, the substance employed being the patient's own blood. The cupping of boils is no new thing, but, according to Dr Kuhn, unless capillary hæmorrhage is produced throughout the whole of the inflamed tissue much of the healing power of the healthy blood is lost Bier's apparatus, he says, with a lift of at most 50–100 mm. Hg, does not break the capillaries, it only draws into the boil what would filter through their walls. Success has been claimed for the injection of the patient's blood around the boil with a needle, but at best the effect is momentary and, in most cases the operation, in Dr. Kuhn's opinion, is useless. His technique is described in an earlier number of the same journal[2] He employs a vacuum powerful enough to induce extensive capillary hæmorrhage, followed by an energetic use of hot packs to promote hyperæmia, and he claims that some boils need only one application of this treatment

In the *Presse Médicale* for March 19th Prof H L Rocher, of Bordeaux, claims excellent results, in cases of cold abscess where no fistula has developed, from lavage with water at 60° C (140° F) He recommends it chiefly for *abcès ganglionnaires*, and articular and bone abscesses, especially those which occur in Pott's disease and in coxalgia Moreover, when the epidermis is on the point of rupturing, this treatment will often prevent a break by thickening and toughening the remaining layers One of its principal advantages is the rapidity with which it takes effect The water is boiled for ten minutes and allowed to cool to 140° F., where it is maintained Hayem's serum may, it is suggested, advantageously be used instead of water The needle or trocar used must be large enough to allow of easy aspiration First of all the collection of pus is withdrawn and then the abscess cavity is well laved with the hot fluid The caseous detritus on the pyogenic membrane is speedily broken up and carried away through the syringe at each aspiration, and by the end of the lavage the membrane is generally bleeding If the evacuated fluid is pink only the process may be continued for another three to five minutes, but if it is red the operation should cease All water should be withdrawn and, if the puncture is so large as to cause anxiety lest a fistula develop, a small poultice should be applied for 48 hours Prof Rocher admits that the treatment is somewhat painful, but not beyond the endurance of the ordinary adolescent or adult, he does not mention what anæsthetic he uses for children. The process has generally to be repeated a certain number of times before the abscess is entirely dry, but some collections, even large ones, disappear after one lavage The method, he claims, gives better results than the injection of modifying liquids, and its simplicity should appeal to the practitioner

THE LATE DR F B POWER

Frederick Belding Power, Ph D, LL D, who died of heart failure on March 30th at Washington, U S A, at the age of 74 years, was an American by birth and upbringing, who spent the most fruitful period of his life in this country, where he was Director of the Wellcome Chemical Research Laboratories from their foundation in 1896 until 1914, when he returned to America to direct the Phytochemical Laboratory at Washington Born at Hudson, New York, Dr Power commenced his association with pharmacy at an early age. He worked as a practical pharmacist in Chicago and Philadelphia, where he was associated with Edward Parrish, of "compound syrup of phosphates" fame He graduated in pharmacy at Philadelphia and again at Strasbourg, where he acted as assistant to Prof Flueckiger In 1881 he was called to the chair of analytical chemistry at the Philadelphia College of Pharmacy, and two years later he established the school of pharmacy at the University of Wisconsin In 1896, at the invitation of Mr Henry S Wellcome, his old class-mate at the Philadelphia College, Dr Power came to England to direct the new Wellcome Laboratories and became responsible for the 168 scientific papers issued from the Laboratories communicated to learned societies during his tenure of office One of his most important investigations was into the active constituents of chaulmoogra and hydnocarpus seeds in the modern treatment of leprosy The value of his work was recognised in the conferment of numerous honours; in 1908 the University of Wisconsin granted him the honorary degree of Doctor of Laws, and in 1913 he was awarded the Hanbury Gold Medal He was Vice-President of the Society of Chemical Industry from 1904–06, served on the council and publications committee of this society, and was awarded the Ebert Prize on three occasions. After his return to America he served on the committee of the United States Pharmacopœia, and in 1920 was elected Vice-President of the United States Convention One of the last honours that was bestowed on him was his appointment as a member of the National Research Council on the Committee of Federal Relations His death removes a figure of international influence in pharmaceutical and phytochemical research

THE LISTER CENTENARY.

FIRST DECLARATION OF THE ANTISEPTIC SYSTEM.

THE first actual revelations of the clinical outcome of the antiseptic doctrines were contained in a series of articles which commenced their course in THE LANCET of March 16th, 1867. Lister's conclusions were based on a series of cases, which, like the one that follows, illustrated for all who could follow his argument the profound revolution which he was inaugurating by bringing the treatment of compound fractures into a position where results hitherto undreamt of could be obtained.

ON A NEW METHOD OF TREATING COMPOUND FRACTURE, ABSCESS, ETC., WITH OBSERVATIONS ON THE CONDITIONS OF SUPPURATION.

BY JOSEPH LISTER, ESQ., F.R.S.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF GLASGOW

THE frequency of disastrous consequences in compound fracture, contrasted with the complete immunity from danger to life or limb in simple fracture, is one of the most striking as well as melancholy facts in surgical practice.

If we inquire how it is that an external wound communicating with the seat of fracture leads to such grave results, we cannot but conclude that it is by inducing, through access of the atmosphere, decomposition of the blood which is effused in greater or less amount around the fragments and among the interstices of the tissues, and, losing by putrefaction its natural bland character, and assuming the properties of an acrid irritant, occasions both local and general disturbance.

We know that blood kept exposed to the air at the temperature of the body, in a vessel of glass or other material chemically inert, soon decomposes; and there is no reason to suppose that the living tissues surrounding a mass of extravasated blood could preserve it from being affected in a similar manner by the atmosphere. On the contrary, it may be ascertained as a matter of observation that in a compound fracture twenty-four hours *after* the accident the coloured serum which oozes from the wound is already distinctly tainted with the odour of decomposition, and during the next two or three days, before suppuration has set in, the smell of the effused fluids becomes more and more offensive.

This state of things is enough to account for all the bad consequences of the injury.

The pernicious influence of decomposing animal matter upon the tissues has probably been underrated, in consequence of the healthy state in which granulating sores remain in spite of a very offensive condition of their discharges. To argue from this, however, that fetid material would be innocuous in a recent wound would be to make a great mistake. The granulations being composed of an imperfect form of tissue, insensible and indisposed to absorption, but with remarkably active cell-development, and perpetually renovated as fast as it is destroyed at the surface, form a most admirable protective layer or living plaster. But before a raw surface has granulated an acrid discharge acts with unrestrained effect upon it, exciting the sensory nerves and causing through them both local inflammation and general fever, and also producing by its caustic action a greater or less extent of sloughs, which must be thrown off by a corresponding suppuration, while there is at the same time a risk of absorption of the poisonous fluids into the circulation.

This view of the cause of the mischief in compound fracture is strikingly corroborated by cases in which the external wound is very small. Here, if the coagulum at the orifice is allowed to dry and form a crust, as was advised by John Hunter,[1] all bad consequences are probably averted, and, the air being excluded, the blood beneath becomes organised and absorbed, exactly as in a simple fracture. But if any accidental circumstance interferes with the satisfactory formation of the scab, the smallness of the wound, instead of being an advantage, is apt to prove injurious, because, while decomposition is permitted, the due escape of foul discharges is prevented. Indeed, so impressed are some surgeons with the evil which may result from this latter cause, that, deviating from the excellent Hunterian practice, they enlarge the orifice with the knife in the first instance and apply fomentations, in order to mitigate the suppuration which they render inevitable.

Turning now to the question how the atmosphere produces decomposition of organic substances, we find that a flood of light has been thrown upon this most important subject by the philosophic researches of M. Pasteur, who has demonstrated by thoroughly convincing evidence that it is not to its oxygen or to any of its gaseous constituents that the air owes this property, but to minute particles suspended in it, which are the germs of various low forms of life, long since revealed by the microscope, and regarded merely accidental concomitants of putrescence, but now shown by Pasteur to be its essential cause, resolving the complex organic compounds into substances of simpler chemical constitution, just as the yeast-plant converts sugar into alcohol and carbonic acid.

A beautiful illustration of this doctrine seems to me to be presented in surgery by pneumothorax with emphysema, resulting from puncture of the lung by a fractured rib. Here, though atmospheric air is perpetually introduced into the pleura in great abundance, no inflammatory disturbance supervenes; whereas an external wound penetrating the chest, if it remains open, infallibly causes dangerous suppurative pleurisy. In the latter case the blood and serum poured out into the pleural cavity, as an immediate consequence of the injury, are decomposed by the germs that enter with the air, and then operate as a powerful irritant upon the serous membrane. But in case of puncture of the lung without external wound, the atmospheric gases are filtered of the causes of decomposition before they enter the pleura, by passing through the bronchial tubes, which, by their small size, their tortuous course, their mucous secretion, and ciliated epithelial lining, seem to be specially designed to arrest all solid particles in the air inhaled. Consequently the effused fluids retain their original characters unimpaired, and are speedily absorbed by the unirritated pleura.

Applying these principles to the treatment of compound fracture, bearing in mind that it is from the occur in attacks with relatively long periods of good digestion between The absence of vomiting and hæmatemesis are of no importance in the diagnosis In gall-bladder dyspepsia pain is present but is " unpunctual " and flatulence or a feeling of " distension " are prominent symptoms The patient is usually a stoutish married woman of middle age Appendix dyspepsia can only be diagnosed with certainty by the results of exploration

---

[1] See Works of J. Hunter, edited by Palmer, vol. i., p. 429.

Diagnostic Aids

Accessory diagnostic aids are furnished by test-meals and X ray examination The test-meal, rarely decisive in ordinary practice, can usually be dispensed with In gall-bladder and appendix cases and in chronic gastric ulcer it is of little help, in chronic duodenal ulcer a high curve is very constant and its absence should throw doubt on the diagnosis, in carcinoma low acidity is the rule but, and especially in an early case, the presence of even free HCl does not negative the possibility of cancer Chronic gastritis is perhaps the only organic condition which can be detected by a test-meal alone (excess of mucus) It is, however, comparatively rare and is certainly too often diagnosed Its treatment does not concern us here

X ray examination, especially if it is done by an expert is of far greater value than the test-meal A negative result however should not be allowed too much weight if the clinical history points the other way It is of most help in the detection of *chronic* ulcers and of carcinoma, but in the earliest stages of the latter even X rays may fail to reveal the disease, and the only method of making a diagnosis early enough to give operation a chance is by exploration Doctors should have the moral courage to insist upon this if the symptoms are suggestive and do not disappear after a month's treatment on functional lines

Visceroptosis is, in women, the cause of much difficulty in diagnosis as its symptoms may sometimes simulate those of organic disease real pain and even vomiting being occasionally caused by it If radiographic investigation fails to show organic disease and if the symptoms persist after treatment for the visceroptosis on the usual lines it may be necessary to resort to exploration

Two Great Groups

Organic disease having been eliminated, the functional cases may be divided for purposes of treatment into two great groups (1) the hypersthenic (hypertonic), (2) the asthenic (atonic)

The hypersthenic cases are commoner in men and are characterised by increase of gastric tone a tendency to pyloric spasm, and superacidity of the contents The asthenic cases are met with chiefly in women, are frequently associated with the presence of gastroptosis and show diminution of tone and motility, and often though by no means always, subacidity of contents The chief symptoms in the hypersthenic cases are " acidity " and hunger-discomfort; in the asthenic group, flatulence, " slow digestion," and a " sinking " sensation when the stomach is empty

In both groups there is a nervous basis In the hypersthenic, nervous irritability and exaggerated reflex excitability, in the asthenic, nervous exhaustion and depression The recognition of the underlying nervous factor is of great importance for it means that *treatment must first be directed to the nervous system* This involves an inquiry into the patient's whole mode of life with the object of getting rid, so far as possible, of all causes of physical, mental, and emotional strain Sometimes it is advisable to send the patient away for a holiday, choosing a bracing inland place for the asthenics and a more sedative one for the hypersthenics In the more severe cases of the asthenic type complete rest in bed may be required along perhaps with abdominal massage and other forms of physical treatment Even in the milder cases rest in the recumbent position for a short time before and after meals is of great value In the abolition of emotional causes of exhaustion psychotherapy is often of help In all cases, whether hypersthenic or asthenic regular meals, well cooked, attractively served, and preferably eaten in company should be insisted upon, but the wholesale extraction of teeth in functional dyspepsia—still too often done—is strongly to be deprecated The dietetic and medicinal treatment in the two groups may be considered separately

Hypersthenic Type

(*a*) *Diet*—In this type the diet must be planned to meet the excess of acidity There are two views as to how this may best be done Some believe in giving foods which " fix " the free acid by combining with it and so rendering it harmless Proteins do this, and so the supporters of this line of treatment allow meat and other animal foods freely Others take the view that the protein foods stimulate the production of gastric juice, and so confine the diet largely to carbohydrates I am an adherent of the first view, and allow meat and other animal foods, but limit starches and sugars Fats are given freely, seeing that they tend to restrain secretion, but all direct stimulants of secretion should be forbidden, chief of these being salt, spices, pickles, and the extractives contained in soups and gravies Alcohol is also a stimulant of secretion Sour things should naturally be interdicted where the acidity is high, and tea (except China) comes under the same ban because of its tannic acid

(*b*) *Drugs*—The drugs useful in this type are those which restrain secretion and relax spasm, those which neutralise secretion, and those which are nerve sedatives Belladonna acts in the first of these ways and may be given in 10 or 15 drop doses in water before breakfast or in a smaller dose before each meal The best antacids are the carbonates of bismuth and magnesia or magnesium oxide, and these may be given in full doses about two hours after meals If the magnesia causes diarrhœa some calcium carbonate may be substituted for it Sometimes it is more convenient for the patient to carry the antacid in the form of a lozenge (troch. bismuth co, absorbent lozenges, &c)

The bromides are the best nerve sedatives, and may be given along with the antacid in such doses as are indicated

The Asthenic Type

(*a*) *Diet*—The diet in this type should be arranged not with a view to the state of the gastric secretion, but in order to suit the impaired motor power Meals should therefore be small, frequent, and dry, for a large meal and the weight of fluid tend to over-distend an atonic stomach Bulky foods such as vegetables (with a few exceptions like spinach, asparagus, and the white part of cauliflower) should be avoided, and so should raw fruits Crisp toast and rusks should be substituted for bread, and potatoes taken sparingly, and only if mashed Articles which stimulate secretion (condiments, &c) are now of use, and alcohol in not too dilute a form may often be taken with advantage at meals

(*b*) *Drugs*—These are of use to stimulate secretion and increase tone, and a mixture of small doses of a soluble alkali (sod bicarb, gr v) with *nux vomica* and a bitter infusion before meals meets most indications The exhibition of acids after meals and of " ferments " of any kind is rarely called for In overcoming constipation, which is often present, the more tonic aperients (aloe, cascara, rhubarb, and senna) should be chosen

ROBERT HUTCHISON, M D Edin, F.R C P. Lond,
Physician London Hospital, and Hospital for Sick Children, Great Ormond street

CHURCH OF SCOTLAND DEACONESS HOSPITAL—The annual cost per bed in this Edinburgh Hospital has increased from £43 in 1914 to £129 Hitherto the institution has paid its way, but last year there was a small adverse balance.

of imperfect pus was produced from the surface of the sore, but not a drop appeared from beneath the skin. It was now clear that there was no longer any danger of deep-seated suppuration, and simple water-dressing was employed. Cicatrisation proceeded just as in an ordinary granulating sore. At the expiration of six weeks I examined the condition of the bones, and, finding them firmly united, discarded the splints, and two days later the sore was entirely healed, so that the cure could not be said to have been at all retarded by the circumstance of the fracture being compound.

This, no doubt, was a favourable case, and might have done well under ordinary treatment. But the remarkable retardation of suppuration, and the immediate conversion of the compound fracture into a simple fracture with a superficial sore, were most encouraging facts.

MEMORIES OF A HOUSE SURGEON *

BY SIR STCLAIR THOMSON,

PAST PRESIDENT, ROYAL SOCIETY OF MEDICINE

"DURING the siege of Paris (1870-71) Nélaton, in despair at the sight of the death of almost every patient after operation, declared that he who should conquer purulent infection would deserve a statue made of gold." This passage occurs in the "Life of Pasteur." One hundred years ago to-morrow, April 5th, 1827, Joseph Lister was born, the man through whose work surgical purulent infection was conquered for all humanity and for all time. There is an indifferent and somewhat neglected bust of him in Portland-place, but the statue of gold has not yet been erected, although wound infection was conquered in Lister's own lifetime. Lister achieved more for mankind than all the surgeons from the beginning of history. Before his coming the results of surgical wounds were hardly better than in the dark ages and yet he lived to see his work and teaching result in the saving of more lives than all the military heroes of all the ages have destroyed.

Lister, a simple and a noble man, could never have understood the spirit of the poet who exclaimed "Let fame which all hunt after be written on our tombs." If, indeed Lister ever had hankered after posthumous fame, it would probably have been the words of Byron he would have quoted: "My epitaph shall be my name alone."

One hundred years ago to morrow Lister was born. Fifty years ago, this year, he left Edinburgh for London. He was then 50 years of age. On the same day that he entered King's College Hospital as one of its surgeons, I entered it as a student—half a century ago. I came under the potent power of his personality. I am poorly prepared to speak of him as a scientific surgeon, and of the miracle he wrought in the history of human suffering. These matters will be dealt with by distinguished exponents during this week of Centenary Celebration. But he exerted on those who came into personal contact with him an influence, a devotion, and an elevation of thought that had in it a touch of inspiration.

Lister was of pure English stock. No one from Scotland, Ireland, or Wales can claim to see a Celtic fringe to the warp and woof of his nature. His people came from Yorkshire. His father was a prosperous wine merchant in the City of London, from whom he inherited other things besides a competence. Amongst these was a taste for scientific pursuits. The wine merchant was deeply interested in the science of optics, he helped to perfect the microscope, and was a Fellow of the Royal Society.

The house where Lister was born and passed his boyhood, Upton Lodge, was in his days quite in the country, in the county of Essex, some ten miles from London, and was surrounded, 100 years ago, with its 69 acres of fields and gardens. It is a charming, substantial, and commodious Queen Anne mansion; it still exists as an oasis beyond the desolation of mean streets which have joined the East-End of the City of London to the borough of West Ham. Refinement and culture still dwell there, for Upton Lodge is now the vicarage of St. Peter's parish, and our Society is delighted to welcome the vicar, the Rev. A. J. Parry.

After attending private schools in Hitchin and Tottenham, Lister entered University College, London, in 1844, at the age of 17. In University College Hospital he was present at the first operation performed in this country under ether, by Liston, on Dec. 21st, 1846. As chill penury did not repress his anxiety to see and know the best in the surgical world, he journeyed in 1853, at the age of 26, to Edinburgh, so as to study under Syme. This great surgeon—to whose memory and teaching Lister always remained devotedly attached—was a man of whom it was said that he never wasted a word, nor a drop of ink, nor a drop of blood. I need hardly say that this thrifty man was a Scotsman! Lister became his assistant, and, a few years later, his son-in law.

From Edinburgh, Lister, at the early age of 33, was called to fill the Chair of Surgery in the University of Glasgow (1861). There he remained until 1869, and it was chiefly during these years that he laid the foundations of antiseptic surgery.[1] In 1869, at the age of 42, he returned to Edinburgh as Professor of Surgery in the University, and there he passed the eight years of his life which he afterwards referred to as the happiest, as they certainly were the fullest and most flowing.

In 1877, exactly 50 years ago, Lister was invited to London. Why did he come south? It was not to hunt for honours and distinctions; his Quaker character thought little of such adornments. It was not due to any mercenary attraction. He was the possessor of a sufficient private fortune, and the commercial side of our profession had no attraction for him. In Edinburgh Lister had many friends; his early years there, his Scotch wife, and his position in the University all were powerful to retain him in the Athens of the north and prevent him from migrating south. But, although Edinburgh students were radiating from the north, imbued with his principles, and although wise men from afar came there and carried to distant lands the glad tidings of great joy, yet still, and for many years afterwards, these principles were inadequately appreciated, were not generally admitted, and consequently their application was still imperfectly carried out. All who knew him are convinced that he accepted the invitation to London simply and solely because he felt that on the larger and more central stage of the metropolis he could so demonstrate his work that he would the sooner fulfil his mission and win the whole world to accept his principles. As his biographer records, "the antiseptic doctrine had been accepted in every part of the world that counted except London, where alone it made but little way." In taking leave of his class in Edinburgh he announced that it was only sense of duty which impelled him to leave a school where he had received great kindness and to take a cold plunge into what he said "might prove to be a sea of troubles."

He was indeed right, a cold and stormy sea of trouble was awaiting him in London 50 years ago. Lister returned from his professorships in two Scottish Universities to his own southern people, to the city of his birth, and the country of his own form of faith. He returned to his own and his own received him not. Many peoples, in all times, have been addicted to stoning their prophets. England and London, half a century ago, were not backward in demonstrating

---

* Address delivered before the Royal Society of Medicine on April 4th.

[1] THE LANCET, 1867, i. 326. In this paper, Lister, after quoting Hunter's observations on healing under a crust, makes his first published references to the researches of Pasteur and to the use of carbolic acid.

vitality of the atmospheric particles that all the mischief arises, it appears that all that is requisite is to dress the wound with some material capable of killing these septic germs, provided that any substance can be found reliable for this purpose, yet not too potent as a caustic.

In the course of the year 1864 I was much struck with an account of the remarkable effects produced by carbolic acid upon the sewage of the town of Carlisle, the admixture of a very small proportion not only preventing all odour from the lands irrigated with the refuse material, but, as it was stated, destroying the entozoa which usually infest cattle fed upon such pastures.

My attention having for several years been much directed to the subject of suppuration, more especially in its relation to decomposition, I saw that such a powerful antiseptic was peculiarly adapted for experiments with a view to elucidating that subject, and while I was engaged in the investigation the applicability of carbolic acid for the treatment of compound fracture naturally occurred to me

My first attempt of this kind was made in the Glasgow Royal Infirmary in March, 1865, in a case of compound fracture of the leg It proved unsuccessful, in consequence, as I now believe, of improper management, but subsequent trials have more than realised my most sanguine anticipations

Carbolic acid[3] proved in various ways well adapted for the purpose It exercises a local sedative influence upon the sensory nerves, and hence is not only almost painless in its immediate action on a raw surface, but speedily renders a wound previously painful entirely free from uneasiness When employed in compound fracture its caustic properties are mitigated so as to be unobjectionable by admixture with the blood, with which it forms a tenacious mass that hardens into a dense crust, which long retains its antiseptic virtue, and has also other advantages, as will appear from the following cases which I will relate in the order of their occurrence, premising that as the treatment has been gradually improved, the earlier ones are not to be taken as patterns

Joseph Lister

A photograph taken at Glasgow in 1868

Case 1 — James G——, aged 11 years, was admitted into the Glasgow *Royal Infirmary* on August 12th, 1865, with compound fracture of the left leg, caused by the wheel of an empty cart passing over the limb a little below its middle. The wound, which was about an inch and a half long, and three-quarters of an inch broad, was close to, but not exactly over, the line of fracture of the tibia A probe, however, could be passed beneath the integument over the seat of fracture and for some inches beyond it Very little blood had been extravasated into the tissues

My house surgeon, Dr Macfee, acting under my instructions, laid a piece of lint dipped in liquid carbolic acid upon the wound, and applied lateral pasteboard splints padded with cotton-wool, the limb resting on its outer side, with the knee bent It was left undisturbed for four days, when, the boy complaining of some uneasiness, I removed the inner splint and examined the wound It showed no signs of suppuration, but the skin in its immediate vicinity had a slight blush of redness I now dressed the sore with lint soaked with water having a small proportion of carbolic acid diffused through it, and this was continued for five days, during which the uneasiness and the redness of the skin disappeared, the sore meanwhile furnishing no pus, although some superficial sloughs caused by the acid were separating. But the epidermis being excoriated by this dressing, I substituted for it a solution of one part of carbolic acid in from ten to twenty parts of olive oil which was used for four days, during which a small amount ever perform satisfactorily the antiseptic treatment of wounds." How far the London surgeons were from being able to appreciate this is shown by an annotation in THE LANCET in 1877 (vol. i., p. 361) which said: "In many quarters Mr. Lister has acquired the reputation of a thoughtful painstaking surgeon and has done some service to practical surgery by insisting on the importance of cleanliness in the treatment of wounds although this has been done by the glorification of an idea which is neither original nor universally accepted."

---

[3] Carbolic acid is found in the shops in two forms—the glacial or crystalline, solid at ordinary temperatures of the atmosphere, and the fluid, which sometimes passes under the name of German creasote The fluid variety is sold in various degrees of purity The crude forms are objectionable from their offensive odour, but the properly rectified product is almost fragrant Different samples, however, differ much in energy of action, and hence, though I have hitherto employed the liquid kind in compound fracture, it would probably be better to use the crystallised form, melting it by placing the vessel containing it in warm water for a few minutes Carbolic acid is almost absolutely insoluble in water, but dissolves readily in various organic liquids, such as the common fixed oils or glycerine

Still, making all allowances, it is difficult to explain why London was the last place to accept the new evangel. The *British Medical Journal* which had always supported Lister writes "of that great principle in surgery, which had been accepted almost everywhere else before it was listened to in London."

But if students and London surgeons were apathetic over the revolution in surgery being wrought in their very midst, it was not so with the foreigners. When I was house surgeon with Lister, 44 years ago, there was in the entrance hall of the old hospital a painted notice board forbidding smoking in English, French, and German. It ran thus:—

> "Smoking is forbidden.
> Il est defendu de fumer.
> Das Rauchen ist verboten."

In 1883 foreigners poured into King's College Hospital, from the ends of the earth crowded the entrance hall and there while waiting for the master, they would make the air thick with tobacco smoke. In later years when Lister's evangel had gone forth over all the earth, and he was neglected by both students and visitors many must have wondered at the need of this polyglot announcement. It survived as a memento of the few early years in London when the prophet was still without honour in his own country, but was attracting from overseas the seekers after truth. Already in 1875, two years before coming to London Lister, during a prolonged tour in Germany, was received everywhere with enthusiasm. In the words of THE LANCET, "the progress of Prof. Lister has assumed the character of a triumphal march" (June 19th, 1875). In 1879 Lister's appearances at the International Congress of Medicine at Amsterdam were greeted with "an enthusiasm which knew no bounds."[3]

At the next International Congress in London in 1881 foreign surgeons must have marvelled amongst themselves when they heard British surgeons still attempting to cast doubts on his principles or belittle his results. But let us in parenthesis project our attention forward to the following International Congress in London. It was in 1913. Lister had died the previous year, but the light of his good work was shining before all men. As is well known, congresses and such like events are often commemorated by the issue of a medal. The medal of 1881 when Lister's work was slighted and belittled by his own countrymen bore the features of Queen Victoria. But in 1913 it was felt in Britain that the one effigy worthy of being stamped on the medal of an International Congress in London was the head of Joseph Lister.

My audience will hardly believe me when I tell them that in my student days the surgeon of one of the largest teaching hospitals—a Fellow of the Royal Society, and a President of the Royal College of Surgeons—frequently raised an appreciative laugh by telling any one who came into his operating theatre to shut the door quickly, in case one of Mr. Lister's microbes should come in.

The first case in which Lister wired a fractured patella was in 1877. When I was his house surgeon I had the honour of bringing together and exhibiting six of the seven first cases which he showed before the Medical Society of London on Oct. 29th, 1883.[4] Some of them were recent cases and others were old, ununited fractures. All were successful. I well remember the astonishment with which Fellows of the Society tried to feel the buried silver wire: but others were aghast at the unwarrantable danger incurred in opening a healthy knee-joint and so running the risk of ankylosis or of amputation or even death. One hospital surgeon, Morrant Baker, asked, "Had not anchylosis, amputation, and death been heard of after its performance?" Another said that if the next case died, Lister should be prosecuted for malpraxis, while a third exclaimed: "C'est magnifique mais ce n'est pas la chirurgie." This bon mot helped, in subsequent years to lessen the reputation of its brilliant author. In those days the peritoneal cavity the pleura, and the synovial cavity of any joint were all sacrosanct spaces and were rarely invaded by the surgeon. Ovariotomy results at King's College Hospital had been so disastrous that the governors had forbidden the staff to undertake it.

Although Lister was carrying out operations never before attempted in the history of surgery, it is interesting to record that I never saw him do an abdominal section. During my term of office we never heard the word "appendicitis": gastric ulcers were diagnosed but never treated surgically; ovarian cysts were tapped and tapped until the patient died; that a calculus could be removed from a ureter or a bile-duct never entered the imagination of the wildest dreamer.

In those early years of Lister's advent a little personal recollection will illustrate how slowly his gospel spread, yet how courageously confident the master was of his mission. One day, in 1883, after he had been six years in London, I was standing beside him on the steps of the hospital waiting (as is the way with deferential house surgeons) for his carriage to pull up. We had been discussing the attack made on him for having the temerity to open a healthy knee-joint. He began by quietly remarking that the day must surely come when the profession would accept the principles of his methods, "and," he added warmly, "if the profession does not recognise them the public will learn of them and the law will insist on them." Then, placing his hand on my shoulder he added pathetically, "Thomson, I do not expect to live to see that day but you may."

Shortly afterwards I went abroad and spent some years on the Continent. To state that I had been Lister's house surgeon served as a *laissez-passer* to make me welcome in any foreign hospital I visited. Everywhere I found Listerian principles had been embraced and his methods pursued with brilliant success. When I settled again in London in 1893 I found the whole surgical atmosphere had changed during my ten years absence. Younger surgeons more open to conviction and less wedded to old routine, had come along and late converts concealed their overdue repentance by rapturously embracing asepsis, and vaunting its superiority over the "antiseptic system" as it was still called. Soon after my return in 1897 the year of Queen Victoria's second jubilee, Lister was made a peer on New Year's Day, his peerage having been the first ever conferred upon a surgeon. In a picture of his coat-of-arms you will notice that the serpent of Æsculapius, for the first time in history, appears in the quarterings of a peer of the realm.

In the following May an address and dinner were offered to him by 30 old house surgeons and 100 dressers. As secretary of that festival I had to make a little speech and took the opportunity of reminding the chief of his words to me on the steps of the hospital 14 years previously, and I pointed out that he had not been imprisoned like Galileo nor burnt at the stake like Giordano Bruno nor crucified like other pioneers of truth, but that he as well as I had lived to see the day when his principles were universally accepted. Then drawing from my pocket a newspaper of that very day, I called attention to the fact that,

[4] Proc. Med. Soc., Lond., 1884, vii, 8.

that a prophet was not without honour except in his own country. His first function was the introductory address of the session on Monday, Oct. 1st, 1877—50 years ago—the first medical lecture I ever attended. The lecture theatre was crowded, and he had a cordial reception from former pupils, distinguished men of science, and many surgeons. But Lister, to most people's astonishment, opened his address by stating that he was going to record some experiments he had made "to obtain some positive and definite knowledge of the essential nature of a class of phenomena which interests alike the physician, the surgeon, and the accoucheur—viz., the changes in organic substance which are designated by the general term fermentation."[2] This address, I well remember, was delivered from behind a table covered with the paraphernalia required to demonstrate Lister's contention that neither milk nor blood have any inherent tendency to putrefaction, and that if either of these fluids was drawn and preserved under what we should nowadays call "sterile conditions," it remained free from putrefaction indefinitely. This, which is all at the present day accepted doctrine, as

'Most can raise the flowers now,
For all have got the seed."
—*Tennyson*

was not so 50 years ago.

When Lister came to London bacteriology as a science was non-existent; the connexion of fermentation and putrefaction with the healing of wounds was unknown or scouted or even ridiculed. If a wound healed by "first intention" it was looked on as an exception, and the rule was that suppuration was Nature's usual process of repair and that pus might even be, as it was termed in those days, "laudable." Anyhow, this first lecture was looked on as a bad start, and altogether unsuitable, for it was generally agreed that such an abstract subject as lactic acid fermentation was no concern of a surgeon. This first plunge in the lecture theatre of King's College was certainly chilly, but it was at the hospital that Lister encountered his full sea of troubles. He had stipulated that he should be allowed to bring with him from Edinburgh four assistants already trained in his methods, and attached solely to his service. This was a cause of offence, because in those days operations were so few that one house surgeon and one operating theatre were sufficient for all the surgeons on the staff.

Of the four who accompanied Lister from Edinburgh to London, one, Dr. James Altham, of Penrith, is dead. Of the surviving three, one is Dr. W. H. Dobie, who has long held a high position in Chester. The two others are with us this evening. One a Highlander in blood and type is Dr. John Stewart, of Halifax, in Nova Scotia. He is one of the most affectionate pupils of the master, whom he has drawn in many letters and pen pictures. The fourth had been Lister's last house surgeon in Edinburgh, and was his first in London. He is with us this evening. He is known to us all as Sir William Watson Cheyne, who succeeded his master as professor in King's College Hospital, became President of the Royal College of Surgeons, served his country on land in the Boer war and at sea in the Great War, reached the rank of Admiral, sat in the House of Commons as Member of Parliament, and is now Lord Lieutenant of Orkney and Shetland. But perhaps his greatest work, and the one I imagine he looks back on with the keenest satisfaction, is his long and loyal service, in hospital and in private work, with the Messiah of surgery, whom he served so faithfully as an apostle to the Gentiles.

The peace-loving Quaker spirit of Lister was also much distressed by the opposition he met with at the hospital from the nursing sisters of St. John. At that date the hospital authorities farmed out, so to speak, their nursing to an Anglican community much given to ritual, frigid rules, repressive formality, and petty restrictions. In the days of Sir William Fergusson the teaching was entirely in the wards; he passed from bed to bed, followed by a sister with a towel and a basin of water, in which he dipped his hands after examining a patient. Lister upset the pious sisters by copious ablutions and the purification of many pairs of hands before a patient was touched and many of his cases were carried or wheeled into the theatre as subjects for clinical lectures. These sisters of St. John were opposed to Lister and all his ways, and dealt him those pious and smiling stabs in which women, particularly good women, are so skilful. Patient, courteous, self-controlled, Lister exhibited no resentment, never retaliated and only showed how he felt it by the little gasping sigh we all learned to know and to respect as his only sign of sorrow or annoyance.

Worse than these two gales in his sea of trouble was what John Stewart describes as the "colossal apathy," the "monstrous inertia to the force of new ideas," the inconceivable indifference shown by the students and surgeons of London. Fifty years ago the wards of most of the hospitals in England reeked with the stench of putrefaction, just as they had done for centuries. But Lister's wards were free from what was everywhere *accepted as the recognised* "hospital smell"; his dressings when taken off were free from pus and fœtor; they were handed round for confirmation, and I well remember the surprised and approving sniff with which the visitor—generally a foreigner—confirmed Lister's frequent and pleased remark: "You will notice, gentlemen that any discharge is only serous and is quite sweet." Yet Londoners did not come to see his epoch making change, to hear, to smell, and to be converted.

In Edinburgh Lister's class frequently numbered 400 students; in London, some 10 or 20 might turn up, but these gradually fell off. Ten years after his arrival Lister referred to his small classes at King's, after his crowded audiences at Edinburgh, as "a humiliating experience." To-day, after 50 years, with new conditions and changed mentalities, it is perhaps superfluous as well as somewhat difficult to explain this neglect. I think the faulty method of teaching and examination had much to do with it. Lister's teaching did not help a man very much to pass an examination and secure a diploma. He was therefore neglected by the average student, while he cast a lifelong spell over those who, as dresser or house surgeon, came under the potent power of his personality.

It is more difficult to suggest the reasons why London surgeons neglected or belittled his work. One was that the discoveries of Pasteur, on which Lister's conceptions of wound infection were based, were too recent, and too little known to be understood as the basis of his principles. Bacteriology had hardly come into existence 50 years ago. Another possible reason was that Lister had, by way of experiment, to try many things in his application of these principles to wound dressing. In these efforts he moved from carbolic lotion to boric, or made trials of corrosive sublimate, and then reverted to carbolic. Or he saturated his gauze with carbolic or iodoform or eucalyptus, or double cyanide of mercury. These frequent changes were all causes for stumbling to the average individual who had not grasped the first principles, and was therefore doubtful of a so-called "system" which was not definite or final (later in history these frequent modifications were counted to Lister for righteousness, for they demonstrated that it was the principle which mattered and not the methods of technique). Another reason was that the surgeons of the latter Victorian period, just like Astley Cooper, Abernethy, and John Hunter, were all in the dark as to how wounds became unhealthy. The generally accepted view was that the air or some "miasm" in it was at the root of the mischief. Surgeons without Lister's scientific training and Pasteurian knowledge looked upon his methods as but another variant of many previous empiric and hopeless efforts. Lister himself realised this, for in one of his addresses he said: "I venture to assert that no one who has not a belief in the germ theory of putrefaction can

---

[2] Brit. Med. Jour., 1877, ii, 465.

German, and in both of these languages I have often heard him speak fluently, easily, and without preparation He was devoted to walking and excursions He was interested in botany and bird life; and he could always fall back on a pocket edition of Horace, Dante or Goethe

Lister's hand was large and neither graceful nor delicate looking, yet he was very neat with his short thick fingers, as is proved by his plastic and soft palate operations, and by the fact that in early days he performed ophthalmic operations We are fortunate in possessing a skiagram of his hand, one of the earliest records of the X ray It does not tell us much, the strength, delicacy, and skill of a hand resides chiefly in the controlling brain He was a steady, firm, and deliberate operator With the least exertion he perspired freely, and it was always one nurse's duty to stand behind him ready armed with a clean towel to which he frequently turned during an operation to mop his streaming forehead

It is interesting to visit the surgical block of the great hospital in Rome the "Policlinico Umberto I" The bas relief in the tympanum over the main entrance shows Lister operating, and wearing a white gown Now, Lister never wore a white gown, nor a mask, nor gloves He frequently never removed his coat, but simply rolled his sleeves back, and turned his coat collar up, so that his white starched collar would not be made sodden by the cloud of carbolic spray in which we operated Sometimes he removed his black frock coat and an ordinary towel was pinned across his chest I myself, for operations, put on an old blue frock coat which I had worn for years previously in the dissecting-room It was stiff and glazed with dry blood Yet our cases, as I remember them, healed as rapidly and as smoothly as they do with all the ceremonial and ritual of sterilisation and asepsis nowadays The operating table served for all cases—sterile or suppurating The floor, also of wood, was made of ordinary deal planks The instruments, which had been carefully washed after they had been last used, were soaked for an hour in 5 per cent carbolic lotion before use; the site of operation had been purified by a wet 1 in 40 carbolic dressing, applied for 12 to 24 hours before operation, the neighbourhood of the operation was cut off by ordinary towels wrung out of warm 1 in 20 carbolic lotion, during the operation any suspicion of "contamination" (as we called it) of hand, instrument, or wound, was corrected by sluicing them with the 1 in 40 carbolic lotion and the whole performance was carried out in clouds of watery carbolic steam which poured over the field of operation from one or two spray machines Lister called the spray an unconscious caretaker It seems to me that the admirable results he obtained—wonderful in the days of 50 years ago and equal to anything done to-day—must, in spite of the surrounding drawbacks I have mentioned, have been largely due to the scrupulous care with which the wound, the instruments and our hands were kept free of "contamination" and the promptitude with which any suspicion of chance contamination was dealt with (One wonders if Lister's principles and teaching were as religiously carried out nowadays whether much of the ceremonial ritual would be necessary, and whether a great deal of the costly construction of hospitals and operating theatres would not be superfluous) On leaving King's College Hospital I became resident medical officer at Queen Charlotte's I was there told that my period of office was the first in the memory of man without a death from puerperal fever For many years I was followed by a succession of residents, all selected from King's men, so that they could continue the antiseptic methods I had introduced there

Lister, this genius, this pioneer, created anew the ancient art of healing He did more for surgery and mankind in his lifetime than all the surgeons of all the ages had effected since the days of Hippocrates I venture to say that, as an instrument in God's hands, Lister has wrought more for the relief of bodily suffering, for the security of life, for the prevention of anxiety, for the conversion of sorrow into joy, for the promotion of happiness, and for the enrichment of mankind than any man who has ever trod this earth The history of our world is divided into two periods, before and since the coming of Christ, B C and A D The history of medicine and surgery and of bodily suffering will always be divided into the times before and after Lister He was our countryman, and the greatest of the masters of surgery, we have lived through the golden age when he evolved this miracle of healing which had waited for centuries for his coming, and now can be wrought by every surgeon in every country in the world Any house surgeon, any newly qualified doctor, can to-day remove pain, arrest disease, and save life by perfectly safe operations which no man knew of, or, knowing, dare not adventure when Lister came to London 50 years ago

Those who chanced to come near this great master caught glimpses of such a spirit as is seldom revealed to us We are fortunate in possessing a perfect portrait of him in imperishable verse, written by W E Henley, who at one time was his patient in the Edinburgh Infirmary

> "His brow spreads large and placid, and his eye
> Is deep and bright, with steady looks that still
> Soft hues of tranquil thought his face fulfil—
> His face at once benign and proud and shy
> If envy scout, if ignorance deny
> His faultless patience, his unyielding will,
> Beautiful gentleness and splendid skill
> Innumerable gratitudes reply
> His wise, rare smile is sweet with certainties
> And seems in all his patients to compel
> Such love and faith as failure cannot quell"

Lister was born a Quaker, but he lived most of his life and died a member of the Church of England. He was blessed with a loving and devoted wife She was the daughter of Prof. Syme, whom he had served as house surgeon in Edinburgh, and she appeared to have no thought or interest beyond her husband She not only loved and shielded him in every way, but entered intelligently into all his work and researches; helped him in his studies; worked in his laboratory; wrote his letters, and always when I arrived at his house in the early morning to go with him to a private operation I would find Mrs Lister preparing and checking off his instruments In their pleasures as in their work they were united They were inseparable companions on all his holidays, and in the numerous Continental trips he loved to make It was while on one of these in Italy that his wife died, after a brief illness in 1893. They had no children, and after her death Lister was a lonely man He lies buried beside her in West Hampstead Cemetery

As illustration of his noble spirit I will give a few sentences from two of his addresses. As a young professor of 33 he told the Glasgow students in his Inaugural Lecture in 1860 that the two great requisites for the medical profession were—"first, a warm loving heart, and secondly, truth in an earnest spirit" Eighteen years later, in a graduation address to newly qualified students, he said: "If we had nothing but pecuniary rewards and worldly honours to look to, our profession would not be one to be desired But in its practice you will find it to be attended with peculiar privileges, second to none in intense interest and pure pleasure It is our proud office to tend the fleshly tabernacle of the immortal spirit, and our path, if rightly followed, will be guided by unfettered truth and love unfeigned In the pursuit of this noble and holy calling I wish you all Godspeed"

In the north transept of Westminster Abbey, as we all can see on Wednesday morning, there is a marble medallion of Lister's bust, placed near to those of the great scientists, Darwin, Stokes, Anderson, and Watt At the public funeral service in the Abbey on Feb 16th, 1912, there was sung an anthem of Handel's to words so peculiarly applicable to our dear master that I cannot better conclude than by quoting them: "When the ear heard him, then it blessed him, and when the eye saw him, it gave witness of him, he delivered the poor that cried, the fatherless, and him that had none to help him.

anyhow, the other part of his prognostication had been fulfilled, for this newspaper recorded that a midwife in Germany had been sent to prison for manslaughter, as she had attended a confinement without providing herself with a proper antiseptic outfit. These intervening years had seen the completion of his mission since he left Edinburgh in 1877, —20 years previously—to take that cold plunge into a sea of troubles. His task was done, and there is little to record of the dwindling years.

In 1892 Pasteur's jubilee was celebrated. Lister was the predominant personality amongst all who came to honour the great French scientist. This event is recorded in a most striking picture, which not only suggests the one-sided feebleness of the semi-paretic Pasteur, leaning on the arm of Carnot (the President of the Republic) but, in a marvellous manner, the artist, Rixens, gives a most life-like representation of Lister's features, his figure, and even of his hands, gestures, and gait. Lister had retired from the active staff of King's College Hospital in 1893 at the age of 66. He was President of the Royal Society from 1895-1900. In 1903, for the first time, his stalwart frame was shaken by a threatening of the infirmities of age. The Continental journeyings he had enjoyed so frequently and so thoroughly were abandoned. His last years were saddened by slowly failing health, and on Feb. 10th, 1912, in his 85th year, he died peacefully at the little fishing village of Walmer, looking out on the English Channel.

What was the personality of this master of surgery? He was tall, upright, well knit, stoutly built, deep chested; his bearing was dignified, and his manner always serious, restrained, courteous, and considerate. He had a profusion of thick iron-grey hair, worn somewhat long, as had been the fashion in his youth. Except for small side-whiskers, he was clean-shaven. I never saw him in any other pattern of collar or necktie than those seen in all his portraits, a black silk bow tie and an upright collar with the peaks turned down over it. His costume never varied; he always wore a frock coat made of the shiny black material called broadcloth, and nowadays only seen on undertakers and country hotel waiters.

His voice was low and musical; there was little resonance or ring, and it had a rather attractive hollowness about it—what, as a laryngologist, I would call a voice of some "phonative waste," due to want of tension in his vocal cords. This tone—or want of tone—in his voice may have been connected with an occasional slight stammer. This trifling hesitation in his speech had persisted from childhood. It was very transitory and never embarrassing. Some thought that the extra effort and emphasis required in overcoming its occasional occurrence added a little charm to his speech, but he himself was very conscious of it, and referred to it as "a severe thorn in the flesh."

His manner was generally serious, but relieved by what Dr. John Stewart calls his "gentle manner and somewhat pensive smile." His manner had a certain aloofness about it. His lifelong disciple, Watson Cheyne, confesses that Lister always inspired him with a certain sense of awe. I myself always felt that his soul was "like a star and dwelt apart," and that, as Wordsworth said of Sir Isaac Newton, his face showed—

> "The marble index of a mind for ever
> Voyaging through strange seas of thought, alone."

Yet he commanded not only veneration, respect, and admiration, but a feeling of complete trust and devotion which could only be explained by the nobility and sincerity of his character.

After a separation of 34 years, his former pupil and house surgeon, John Stewart, could write: "It is beyond my power to express the feelings of reverence and love I have for Lord Lister, or to say how much his life has been to me." For my own part I can only say that no teacher, no friend, no man I have ever known has left his impress on me as Lister has done. To none of them do I feel the debt I owe to him, for the example of his veracity of thought and word, his patience under persecution, his constancy in the pursuit of truth, his eagerness to instruct his pupils, his long-suffering with stupidity, his tenderness to the poor and his gentleness to the sick and maimed. He was imbued, I need hardly say, with a truly scientific spirit. His studies in physiology and pathology and their bearing to clinical surgery will be referred to in addresses by experts during this centennial week. He urged the necessity of experimental and laboratory research. In 1875 Queen Victoria, to whom only one side of the question had been presented, wrote requesting him to take action for the suppression of vivisection. Although he held a court appointment he had the courage to decline an invitation he could not conscientiously accept. He wrote to her private secretary as follows: "I should deeply regret that I cannot see my way to comply with this request, were I not persuaded that my doing so would not promote the real good of the community, which I know to be Her Majesty's only object in the matter."

In the same way, although he used all the cases in his service very freely for class demonstration and instruction, his patients never resented it—were even proud of it—for he never neglected to let them feel that they were regarded as fellow human beings as well as so-called "clinical material." One of his sayings was, "The individual patient asks to be relieved and not to be studied," which reminds us of the great saying of a Frenchman: "L'amour de la médecine fait le savant, l'amour du malade fait le médecin." To demonstrate his consideration and kindness to everyone, I will throw on the screen a facsimile of a letter written by Lister to the house surgeon who preceded me, the late Dr. R. G. Lynam, of Oxford. It will be noticed that the letter is entirely concerned with the interests of his students and a hospital patient, for whom he shows a touching consideration. He sent the letter to the hospital by special messenger, there being no telephone in those days. Typewriting machines were also in their infancy, and you might think that this written letter had all been penned by Lister, so similar is the signature of the body of the text. As a matter of fact it was like most of his letters, written by his wife, and only signed by him. Here is another instance of his singlemindedness and honesty. Like all great men he was keen on the importance of small details. In showing us how to bandage a breast he insisted on the point that, in spite of various turns, the bandage was almost sure to slip and allow a dressing to be displaced if the transverse turns of the bandage, above and below the prominence of the mamma, were not prevented from slipping up and down by uniting them with a safety pin, which securely prevented them from drifting apart. To impress this point upon us he narrated that he had once had to open a simple abscess in the axilla for Queen Victoria. All went well. After one dressing and on arrival at the railway station to travel back to Edinburgh, he suddenly remembered that he had forgotten the important safety pin. He at once drove back to the Castle, and explained his oversight to Her Majesty, and the necessity for rectifying it. Some surgeons, I fear, would have thought first of their own reputation, and would have "risked" the safety pin.

He felt checks and disasters very keenly at the time, but a certain buoyancy soon restored his equanimity and forward-looking temperament. He himself writes this when on a holiday: "I have the happy faculty of being able to throw off all thoughts of work for the time being." He fished, but as his biographer remarks, he was a diligent amateur but never an expert. He skated and could do 8's and 3's—but of small dimensions. He took a fair share of vacation, and on his holidays could be light-hearted and boyish. But complete idleness was not congenial to him; on his holidays there were usually proofs to correct, or addresses to prepare. On the Continent he practised and improved his very good French and at Hampstead by the side of his wife after a most impressive service in Westminster Abbey Like Pasteur, and more fortunate than many reformers and pioneers Lister lived to see his work bear fruit exceedingly, and died full of years and loaded with honours from all countries but it is as the greatest material benefactor of the human race, who made surgery safe and thereby did more than any other man to prevent suffering and save life that we regard him with deep gratitude and thankfulness

THE CONQUEST OF SEPSIS[1]

BY SIR JOHN BLAND-SUTTON, BART,

LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

CENTENARIES remind us of our predecessors and reawaken our memories to the benefits we derive from their discoveries The discovery of the anæsthetic properties of ether and chloroform 80 years ago is a landmark in the history of surgery, and it is common knowledge that 20 years later surgical operations increased enormously in number in all big cities and postoperative sepsis became so common and so mortal as to threaten the extinction of operative surgery as an art Endeavours to ascertain the cause of sepsis exercised the minds of the greatest surgeons

The principles underlying the treatment of wounds were based on the idea that festering was due to something which entered wounds, and the time-honoured methods adopted in treatment consisted in removing any foreign body that might be in the wound to staunch the bleeding usually with the aid of styptics, then close the wound and allow it to heal The styptic might contain something to stimulate the healing process This method of treating wounds can be traced back 3000 years it was practised by famous physicians in the Trojan war

All who are acquainted with Virgil's Æneid can recall this stirring story When the hero Æneas was wounded in the thigh with a dart, the celebrated Trojan physician Iapyx *came to aid him After some* trouble the head of the dart was extracted and Iapyx instilled into the wound a tincture to which the goddess Venus added unknown to the physician, some juice prepared from the stalk, leaves and flowers of dittany from Crete Suddenly all pain fled from the wound and all the blood in the deep wound was staunched Æneas soon recovered his vigour and urged by Iapyx, returned with zest to the fight

In 1866 a patient was admitted into the Glasgow Royal Infirmary with a compound fracture of the leg and had the good luck to come under the care of Joseph Lister the professor of surgery who treated the fracture on the same principles as Iapyx treated Æneas but instead of a tincture containing dittany he instilled into the wound a solution of crude carbolic acid There was nothing poetical in this, but the result exceeded Lister's expectation for the patient recovered with a useful limb The usual treatment at that time was amputation and even in such an event the patient usually died from sepsis The successful issue in this case was of the utmost importance for it laid the foundation of the glorious edifice of Antiseptic Surgery

The treatment adopted by Lister in this instance was no sudden inspiration When he served as Syme's assistant surgeon in Edinburgh in 1856, postoperative sepsis was endemic in every infirmary and hospital in the British Isles Lister attributed sepsis to something which entered wounds He believed that putrefaction was caused by the oxygen of the air, chemists believed this Lister thought that sepsis could be communicated to wounds by instruments, sponges and the fingers of surgeons and attendants He devised means for preventing infection and selected carbolic acid at that date called creosote, a chemical novelty used for deodorising sewage, for the purpose of destroying the agents of sepsis, and he adopted the word Antisepsis for his method Whilst Lister was busy with these investigations Cohn made the important discovery that yeast was a microscopic plant Pasteur discovered that fermentation and putrefaction were due to the action of microbes Lister welcomed Pasteur's demonstration "that putrefaction like other true fermentations is caused by microbes growing in the putrescible substance" These brilliant discoveries proved that the apparently dissimilar processes—fermentation, putrefaction, suppuration and sepsis—are due to the action of minute living organisms

Pasteur's discovery revolutionised the methods of the winepress, brewery, dairy, and sewage farm, Lister's transformed the methods of operative surgery, and they are by *no means* limited to mere wound treatment, they have led to extraordinary changes in surgeons, hospitals, and lying-in chambers All great changes introduced into an ancient craft stir up opposition and ridicule Some cautious surgeons who laughed at antisepsis endeavoured to follow the method Others who jibed went slowly, but surely, to the wall

In the face of opposition Lister pursued his course apparently unruffled The younger surgeons—enthusiastic converts—adopted his principles and gradually introduced the methods of the bacteriological laboratory sterilisation by heat This ultimately became the Cult of Asepsis Indeed, heat is the most perfect antiseptic known Odoriferous carbolic acid persists as a memory!

Since 1900 operative surgery has advanced with such strides that text-books of surgery have become like railway time-tables, useful only for a season Surgical methods change monthly Operating theatres which resembled shambles in 1860 are replaced by rooms of spotless purity containing scintillating metal furniture and ingenious electric lights All concerned in the operation are clothed from nose-tip to toe-tip in sterilised linen garments, and their hands covered with sterilised rubber gloves The patient is in a sleep as deep as that of Adam in Eden, and the theatrical silence is only broken by the rhythmical breathing of the patient or an occasional utterance from a nervous operator Modern surgery is wonderful I was trained in the old school and lived to revel in the wonders of the new But this is not the end, the legitimate function of surgery is the repair of physical injuries We must strive to cure morbid growths with drugs prepared by biochemists We may believe that chemotherapy and physics which have furnished surgeons with powerful and reliable remedies, will help to deliver mankind from some of the most distressing and unpromising operations of modern surgery.

There are clear signs of the dawn of such an era The dominating features of Lister's life were his persistent enthusiasm and faith for the cause he had at heart; and his courage in the face of the incredulity of contemporary surgeons is beyond all praise The propagation of a New Gospel in religion science or art demands forceful disciples If Lister had had an apostle with the zeal of Saul of Tarsus or a disciple with the eloquence of Huxley the Listerian principles of wound treatment would have been universally accepted before 1900 In spite of this Lord Lister had the rare privilege of living to see his principles adopted by surgeons throughout the world

The bronze figure of Lord Lister in Kelvingrove Park exemplifies his steadfastness in the pursuit of Truth, the granite block which supports it is typical of the firm foundation on which his discovery rests The monument is an expressive tribute to the great surgeon whose influence will remain as long as surgery is practised as an art and the conquest of sepsis will continue to be a blessing on every race of mankind

---

[1] Address delivered at the Lister Centenary Celebrations in Glasgow

Kindness, meekness and comfort were on his tongue. If there was any virtue and if there was any praise, he thought on those things. His body is buried in peace, but his name liveth for evermore."

A DOMESTIC SURVEY [1]

By Sir HUMPHRY ROLLESTON, Bart.,

LATE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

We are here to commemorate the centenary of one of the greatest benefactors of mankind, Joseph Lister, born on April 5th, 1827, at Upton House at Upton in Essex, then hardly even a village, now swallowed up in this great city and in the Borough of West Ham which has the honour of having had him as a Freeman.

He was the fourth child and second son of Joseph Jackson Lister (1786–1869), who had a world-wide reputation for his discoveries in optics and the perfecting of the modern microscope by achromatic lenses, thus becoming a Fellow of the Royal Society of which his son was destined to be President. Arthur (1830–1908), another son of Joseph Jackson Lister, was also a Fellow of the Royal Society and distinguished for microscopical research, writing with his daughter Gulielma a monograph on the Mycetozoa; one of his sons, the late Joseph Jackson, was also a Fellow of the Royal Society, and another, Sir William Tindall, is ophthalmic surgeon to the adjacent London Hospital. The Becks, connexions of the Lister family, were well known as opticians. The late Sir Rickman Godlee (1849–1925) who wrote the life of his uncle Lord Lister, was President of the Royal College of Surgeons of England. The scientific record of the Lister family is therefore remarkable.

The Listers belonged to the Society of Friends, founded by George Fox in 1643 who in 1650 admonished Justice Bennet of Derby and those present to quake at the name of the Lord, hence their alternative title. Being debarred by their religious tenets from the older universities, from taking holy orders, and joining the fighting forces, and by cutting themselves off from vain sports and places of diversion, such as hunting theatres, and music, the Friends were much given to education and to the study of science and natural history. Thus a relatively large number of them became Fellows of the Royal Society. The Quaker atmosphere of quiet goodness, which originated so many of the philanthropic movements of the nineteenth century, and the study of nature admirably fit the members of the Society of Friends to minister to the sick and there have been many famous medical men among them. The greatest man of genius who ever entered the medical profession was Thomas Young (1773–1829), "alike eminent in every department of human learning," who foresaw X rays and electrons, was, like Lister's father, a pioneer in optics; and, like Lister again shed the external observances of the Society of Friends when working in Edinburgh. Among other well-known Quaker medical men were Thomas (Baron) Dimsdale, who, in 1768, successfully inoculated Catharine Empress of Russia against small-pox; John Fothergill, whose country seat with its wonderful gardens was Ham House close to Upton House, Thomas Hodgkin (1798–1866) who described what is now known as "Hodgkin's disease," and founded the Aborigines Protection Society, and more recently Sir Jonathan Hutchinson of the London Hospital, a contemporary of Lord Lister's. None of the Lister family, except a distant cousin had been a doctor, but when a child Joseph Lister had decided for himself that he would be a surgeon, and this desire strengthened with his age; his father though not encouraging this ambition, wisely left his son to work out his own salvation, and as it resulted that of his fellow men.

Joseph Lister was educated at Quaker private schools at Hitchin and Grove House, Tottenham, and in 1844 entered University College, London, which is this year celebrating its centenary. Here he worked for nine years, being a spectator of Robert Liston's first operation under a general anæsthetic in 1846, and having many opportunities of watching the ravages of erysipelas, blood poisoning, and hospital gangrene, then the unavoidable accidents of surgery. In 1853 he went to Edinburgh, originally for a short visit, but remained for seven years, marrying in 1856 Agnes, daughter of James Syme, whom he was destined to succeed in the professorial chair.

The two great events in the history of surgery are the introduction in 1846 of anæsthetics, which made surgery possible, and has been called "the death of pain," and the discovery of the antiseptic and aseptic method dating from 1867, which has made surgery safe for humanity and may in like manner be termed "the death of infection." In 1865, which may therefore be called the birth year of the antiseptic method, Lister began the campaign to prevent germs in the air from getting into wounds and so, by the resulting blood poisoning, rendering operations a most perilous form of treatment. Lister had long been thinking and preparing how to obviate the risks of the diseases which attacked patients after operations, but the discovery in 1865 that germs of micro-organisms caused putrefaction was made by the great Louis Pasteur, who was a chemist not a medical man, really showed him the way. Most surgeons if they heard of Pasteur's researches would have been mildly interested in them, but Lister was able to grasp their significance and henceforth devoted his life to applying this principle to the prevention of post-operative infection. His brilliant imagination, philosophic insight, untiring industry, and unflinching courage overcame the antagonism, not to mention ridicule, that his life-saving work provoked and he finished his task. In 1867, just 60 years ago, Lister published his first papers on antiseptic surgery, and from that time he continued by most careful and indomitable research to improve the methods.

It is almost impossible to describe the world-wide transformation of surgery which was brought about by Lister's work. The history of surgery has indeed been divided into two periods, that before and that after Lister's methods became adopted; before his discovery as few operations as possible were done because of the risk that they would be followed by erysipelas, blood poisoning, pyæmia, hospital gangrene, tetanus and death; abdominal operations, such as are so constantly done now for appendicitis, were practically unknown; to open a large abscess was almost certainly to sign the patient's death warrant. Hospitals indeed were spoken of as "houses of death."

Lister, who was professor of surgery in Glasgow from 1860 to 1869, became professor of clinical surgery in Edinburgh in succession to his father-in-law James Syme, and there continued to practise, preach, and perfect the doctrine of antiseptic surgery. Like most great advances and reforms, this life-saving discovery met with much opposition and criticism, and in order to overcome these adverse influences and to spread the knowledge of the correct method of carrying out the antiseptic treatment, he accepted in 1877, when 50 years old, an invitation to be professor of clinical surgery in King's College, London, for be it said, with regret, his native city was the stronghold of antagonism. His London life falls into two almost equal periods; from 1877 to 1893 he was a busy hospital surgeon gradually convincing all of the inestimable value of the antiseptic methods; in 1893 his retirement from the hospital, on account of age and the sudden death of his devoted wife, leaving him a childless widower at the age of 66, entirely altered his life. Henceforth, with rare nobility of character he devoted himself to public duties; he became President of the Royal Society in 1895 in succession to Lord Kelvin, and President of the British Association in 1896, giving his address on "The Interdependence of Science and the Healing Art." He died on Feb. 10th, 1912, at Walmer, and was buried wrong with an operation the surgeon did not blame this or that material he had used, or any of his helpers; he asked himself what he had himself left undone.

---

[1] Address delivered at Lister's Birthplace, Upton, on April 5th.

Sir Watson Cheyne continued: "It is just 50 years ago since Lister received an urgent invitation from the authorities of King's College Hospital then situated in the vicinity of Lincoln's Inn-fields asking him to go to London to fill the place in that hospital which had become vacant by the death of Sir William Fergusson in the preceding year. This request came as a thunderbolt to Lister. He had settled down in Edinburgh and was supremely happy in his life there. He had many friends who loved and admired him, not only for his ability but also for his gentleness and sympathy with suffering and readiness to help. His wife was a native of Edinburgh and had all her friends and relatives there. He had very large classes of enthusiastic students and it was a great joy for him to teach them; his students loved and worshipped him and they were violently opposed to the attempt to get Lister to leave Edinburgh. At first Lister declined the proposal, but renewed requests of the most urgent nature made him ultimately agree to go to London, being chiefly influenced by the argument that his views and methods of treatment would spread more quickly from the metropolis than from Edinburgh, and by the fact that although something like 11 years had elapsed since his first publications there were really very few surgeons in London who had taken up his methods, and that these methods were opposed and derided by many men of great ability. Comfort and happiness were for him matters of little consequence as compared with the rapid adoption of his teaching by surgeons in general.

"I remember well this time 50 years ago, for only a day or two after Lister had received the invitation, and before he made his vital decision, he came down to the Edinburgh Infirmary early one morning and woke me up (I was his house surgeon at the time) to ask whether, if he decided to go to London, I would go also and again act as house surgeon so as to start the treatment at King's and to teach the students; you can well understand that I was considerably excited at the prospect of migrating to London. Three other students were also asked to go as clerk and dressers—viz., Stewart, Dobie, and Altham—and they were equally excited and pleased at their selection to follow the master. You can well believe that we looked on our selection as an unexpected and unbelievable honour. No question of self had play, either in the chief's mind or in ours. We all felt as the old Crusaders must have felt and our only aim was to do our part of the work as carefully as we could so as to show those who were lagging behind how true was every claim made for Lister's methods.

"Whether Lister was right or not in accepting the London invitation is a very debatable point. Possibly his views did penetrate more quickly than from Edinburgh, but Lister missed the large number of students who followed him and filled the large lecture room in Edinburgh, and at times when the students at King's College (then quite a small school) who came to the lectures were few, or looked bored, he was very pessimistic. It is well known to all lecturers how much better a lecture is if there is a large and enthusiastic audience rather than a scanty and, apparently, unappreciative one. For some years I attended his lectures whenever I could manage to go, as I knew how much the presence of senior men pleased and comforted him. I thought for a considerable time that we had struck a poor type of student, and was very unhappy about it, but I found later on that the examining bodies did not favour "Listerism" and that the students were afraid to introduce the subject and hence did not want to learn his views till after they had passed their examinations. However, a good many men who were able to do so took an extra course or stayed behind after passing the examinations so as to see Lister's practice.

"I think one of the greatest, if not *the* greatest, characteristics of Lister was this extreme conscientiousness in his actions and in promulgating his views so constantly displayed in his writings, and particularly well shown when he got the invitation to this hospital. There is considerable difference of opinion as to whether his choice was right or wrong, but the decision was only taken after prolonged consideration of the matter. This care to get at the truth runs through all his work; it is very noticeable in his scientific papers and especially in his addresses. His care in this direction—viz., to ensure as great accuracy as possible—had the curious result that, when he had to deliver any important address, he was almost certain to arrive late at the meeting; the explanation being that, on going over the points of his discourse before leaving his house, something was very apt to occur to him as not sufficiently proven to justify his making a positive statement, and he would, even at the last moment, set to work to look into the matter. It is narrated of him that when he was delivering the Croonian Oration at the Royal Society on the coagulation of blood, a point struck him after he had left his home and he turned into a slaughter-house, had an animal bled, and made the necessary observation before going further; he was in consequence a good many minutes late. Another example of his conscientiousness was the way in which he dealt with his patients, whether private or in the hospital. If, on visiting them, they complained of pain or discomfort, however slight, he would set to work to rearrange the dressings, splints, pillows, &c., irrespective of other engagements; and this was very apt to make him late for appointments and so, contrary to what one would have expected, he never had a large private practice, as practitioners were too busy to make appointments with him, seeing that these appointments might not be punctually kept. In another way this conscientiousness troubled him a great deal—for example, when he was asked to give an opinion in a case on which he himself was not to perform the operation if one were decided on. In many cases the opinion that he felt to be the correct one might depend entirely on whether the wound would remain aseptic or not. If he advised an operation in which asepsis was essential and the operation was not done by him or by someone who believed in and practised asepsis, his opinion, if acted on, might practically condemn the patient to death. In this transition period he therefore quite rightly looked on an opinion given by a surgeon as only applying to his own handling of the case, and he was very much against those who give advice after they have ceased to operate.

"Yet another example of Lister's conscientiousness I can give personally. When my eldest son was born, I asked Lister if I might call him Joseph Lister and if he would be godfather to the child. I candidly admit that I was not familiar with the activities of a godfather, but thought that it was a purely ornamental matter. In answer to my request he replied that he would like to consult Lady Lister first; the next day I received a letter from him saying that they would be very pleased to have the boy called after him, but that his life was so full and busy that he could not undertake further duties such as those of godfather. Apart from this conscientiousness Lister was full of sympathy with sufferers, and was always ready to do what he could to relieve suffering and to help those in need. One has only to look at his portraits to see these characteristics beautifully depicted. His readiness to help became well known and was sometimes much abused. Quite a number of supposed German professors who had come over to England to study lost their libraries on the voyage and came to Lister for help, which they obtained most generously; but as time went on he found that this purchase of libraries was a severe drain on his pocket.

"In spite of the numerous ovations which Lister received on all hands there was no affectation or

THE CENTENARY CELEBRATIONS

The Centenary celebrations commenced with the reception by the King at Buckingham Palace of about a hundred delegates from all parts of the world. Among them may be mentioned —

Foreign Countries

The Argentine Minister (Argentine), Dr Otto Stapf, (Austria), Prof Dr Vilhelm Schaldemose (Denmark), Prof Ali Krogius (Finland), Dr Pierre Bazy, Prof Henri Hartmann, Dr Pasteur Vallery-Radot (France), Prof Dr Max Ritter von Gruber, Prof Dr Albrecht Kossel, and Prof Dr Max Rubner (Germany), Prof Dr C F A Koch (Holland), Signor Roberto Allasandri (Italy), Prof Johan Nicolaysen (Norway), Prof Casimir Kostanecki (Poland), Sir Arthur Schuster F R S (Spain), Prof S Gustaf Hedin (Sweden), Prof F de Quervain (Switzerland), Prof Melvin S Henderson, Prof Dean de Witt Lewis, and Prof William George Maccallum (United States of America)

Overseas Dominions

Prof Kerr Grant Mr R Hamilton Russell (Australia), Prof Irving H Cameron (Canada), Major-General J B Smith, I M S (India) Prof Daniel Colquhoun (New Zealand), and Dr W Watkins-Pitchford (South Africa)

British Delegates

Sir John Rose Bradford (*President*, Royal College of Physicians, London), Sir Charles Sherrington (Royal Society of London and Italy) Sir Berkeley Moynihan (*President*, Royal College of Surgeons of England), Prof George M Robertson, (*President*, Royal College of Physicians Edinburgh), Mr A Logan Turner (*President*, Royal College of Surgeons, Edinburgh), Prof Andrew Fullerton (*President*, Royal College of Surgeons in Ireland), Dr George H Edington (Royal Faculty of Physicians and Surgeons of Glasgow) Sir George Newman (Royal Society of Edinburgh and The Ministry of Health), Prof J Graham Kerr (Royal Philosophical Society of Glasgow), Sir Archibald Garrod (University of Oxford) Sir Humphry Rolleston (University of Cambridge), Prof Percy T Herring (University of St Andrews), Prof Archibald Young (University of Glasgow), Prof John Marnoch (University of Aberdeen) Sir Harold Stiles, (University of Edinburgh), Sir William Taylor (University of Dublin), Sir Holburt Waring (University of London), Mr George Grey Turner (University of Durham), Prof F Craven Moore (University of Manchester), Prof Alfred W Sheen (University of Wales) Prof Leonard P Gamgee (University of Birmingham), Prof William Thelwall Thomas (University of Liverpool), Prof J Kay Jameson (University of Leeds), Prof Edward Mellanby (University of Sheffield), Prof Edward Fawcett (University of Bristol), Colonel Thomas Sinclair (Queen's University of Belfast), Surgeon Vice-Admiral Sir Joseph Chambers (Navy Medical Service), Lt -General Sir Matthew Fell (Army Medical Services), Air Vice-Marshal David Munro (Royal Air Force Medical Services), Sir Walter Morley Fletcher (Medical Research Council), Lord Somerleyton (King Edward's Hospital Fund for London), Dr Eustace M Callender (Medical Society of London), Sir Edward Sharpey Schafer (British Association for the Advancement of Science and the Physiological Society), Mr Robert George Hogarth (*President*, British Medical Association) Sir James Berry (*President*, Royal Society of Medicine), Sir Cuthbert Wallace (Association of Surgeons of Great Britain), Sir James Kingston Fowler (Lister Institute of Preventive Medicine), Sir Frederick Andrewes, F R S (Pathological Society), Dr John Cowan (Royal Medico-Chirurgical Society of Glasgow), Dr James Alexander Murray (Royal Microscopical Society) Sir Frederick Fry (Merchant Taylor's Company), Mr Alfred Hepburn (*Master*, Society of Apothecaries of London), Prof James Peter Hill (University College, London), Dr Ernest Barker (King's College, London), Dr Herbert Morley Fletcher (St Bartholomew's Hospital), Mr Charles Gibbs (Charing Cross Hospital), Mr Walter Fedden (St George's Hospital), Mr Francis James Steward (Guy's Hospital) Mr Arthur Cheatle (King's College Hospital) Prof William Bulloch (London Hospital), Dr Charles M Wilson (St Mary's Hospital), Dr Eric Pearce Gould (Middlesex Hospital), Mr Cyril A R Nitch (St Thomas's Hospital), Dr Archibald M H Gray (University College Hospital) Mr William Turner (Westminster Hospital), Lady Barrett (London School of Medicine for Women) Dr George Mackay (Royal Infirmary, Edinburgh), Mr William George Black (Royal Infirmary, Glasgow), Colonel Donald James Mackintosh (Western Infirmary, Glasgow)

An address was presented to His Majesty by Sir Ernest Rutherford, the President of the Royal Society, in which the work of Lister was described as having effected more for the saving of human life and the prevention and relief of suffering than the scientific activity of any one other man The speaker described Lister as one of the greatest benefactors of the human race, while pointing out the brilliant qualities for investigation that had been necessary in applying the discoveries of Pasteur to the problems of antisepsis and developing modern surgery from that basis The King in reply said —

" I thank you for the address which you have presented It is with pleasure that I receive the delegates who are present here to-day, and so take part in the Centenary Commemoration of Lord Lister's birth Any country might be proud to claim Lord Lister as its citizen, and I and my people heartily welcome the representatives of medical and surgical science, both from the Overseas Dominions and from all parts of the civilised world, who have come to join us in honouring his memory

" You have truly said that Lister ranks among the greatest benefactors to mankind Of all the many changes in the last 100 years none is more striking than the revolution in thought concerning surgery It is hard now to realise the dread and apprehension with which formerly even a minor surgical operation was regarded This change in our ideas is due partly to the discovery of anæsthetics and perhaps even more to Lister's work Lister removed the horror of sepsis from surgical operations, and for this he is rightly described as the father of modern surgery The principles discovered and laid down by him are to day being worked out by his successors and are still fruitful of new applications

" Naturally a layman looks first at the ultimate success and beneficent effects of Lister's work These, however, were not the outcome of happy accident or sudden inspiration, but of long and patient study, of continuous experiment, and finally of a wide knowledge and penetrating insight, enabling him to discern the importance and practical bearing of observations which, to some minds, might have remained a piece of academic research

" It is my earnest desire and hope that the Lister Centenary Celebrations may be in every way successful, and that this gathering of men of science from every quarter of the globe may conduce to foster and to strengthen the cooperation of all nations in the accumulation of scientific knowledge for the common benefit of the human race "

Celebration at King's College Hospital

Address by Sir Watson Cheyne

A large gathering assembled in the Refectory of King's College Hospital on Monday afternoon, April 4th, under the auspices of the Listerian Society, when the chair was occupied by the President of the Society, Mr Arthur Cheatle

The President, in extending a warm welcome to the speakers and others who had known Lord Lister said this centenary was being kept with gladness and with the deepest gratitude and pride, gratitude that such a man had been born into the world to do such a glorious work, and pride because he was a fellow-countryman and was closely attached to King's College Hospital, as surgeon and consulting surgeon for 35 years Exactly 50 years ago he was President of this Society

Sir W Watson Cheyne said that some who had assembled to do honour to the memory of the master he, the speaker, had not seen since they left the hospital, and it warmed his heart to see them again It was during the 16 years spent in this hospital that Lister completed the simplification of his methods of treatment, without in any way altering the principles on which those methods were founded. Lister's work was more widespread in its results than that of any other great man, for its influence on mankind was not limited to any country or any race, the number of lives saved and the amount of suffering and ill-health prevented by it was incalculable So sound were the principles that if anything went

Commemoration Service at St Peter's, Upton Cross, Essex.

A service was held at St Peter's Church Upton Cross on April 5th to commemorate the birth of Lord Lister at Upton House now St Peter's Vicarage on April 5th 1827 The Bishop of Chelmsford preached the sermon and Sir Humphry Rolleston delivered an address which we print on p 780 A procession to the church from the vicarage was formed the Lord Provost of Glasgow the mayors and medical officers of health of local county councils and boroughs representatives of local hospitals and members of the medical profession taking part The Rev A. J Parry vicar of St Peter's has prepared a brief account of Lister s life and work, which was distributed to those attending the service

Reception at the Royal College of Surgeons of England

On the afternoon of Tuesday April 5th the President and Council held the Lister Birthday reception within the walls of the Hunterian Museum A brilliant throng of foreign delegates and leaders of the medical profession from the Dominions overseas and from Great Britain and Ireland. with their ladies were gathered soon after four o'clock in the Museums Library and Council Room of the College being received in the entrance hall by Sir Berkeley and Lady Moynihan and members of the Council In Room I of the Museum the centre of interest was a display. arranged by the Conservator and Librarian. of the manuscripts documents and printed books contained in the Lister Memorial Cabinet of which some account has been given in THE LANCET recently (March 12th, p 553) Among the manuscripts priority should be given to the volume labelled by the late Sir Rickman Godlee "Notes and Drawings Suppuration. Lister. 1851-1907" The folio lay open at the page where Lister in his own rapid and oft-corrected script had placed on record a detailed history of the first case in which the carbolic acid antiseptic dressing was used The patient a boy suffering from a compound fracture of the femur was treated by Lister in his famous Glasgow Ward, in 1865 and though this first experiment proved unsuccessful—relatively so, for the boy does not seem to have died—it marked the beginning of antisepsis, being followed by operations of beautiful perfection Close by this famous volume were also displayed Lister s wonderful drawings of fungi while on a screen were hung Listerian diagrams illustrating the earliest test-tube experiments on bacteria so carefully recorded by the great surgeon in his "Common-Place Books' Four volumes of these now first shown in public, will continue to be one of the glories of the Hunterian Collection One of the diagrams which seems to have been used by Lister in his lectures illustrates *Torula cerevisiæ* and *Bacterium lactis* as also the bacteria found in urine In the Conservator's room two drawings by Sir Rickman Godlee were shown illustrating micro-organisms in the pus of a newly opened abscess first observed and recorded on May 20th 1871 Other exhibits of supreme importance were Lister s own copy of *Palmer s Life of John Hunter* with Lister s notes on two of the title pages and a slim volume containing five letters from Lister's famous precursor Louis Pasteur who inquires in 1871 concerning the exact nature of the bacteria which the distant Englishman has observed in wounds Pasteur avers that he has long heard with interest of Lister s work but reading between the (alas !) rapidly-fading lines of the great Frenchman s manuscript one cannot help surmising that he thought his English disciple somewhat hyperborean Be that as it may the little letter-book is without price Sir William Watson Cheyne s work with Lister at King s College in 1878 is attested in this exhibition by a very interesting MS of Lectures and by three charts chosen from a number illustrating the escape of blood from the jugular arteries of animals

The Dinner in the City to the Delegates

On Tuesday, April 5th, a dinner was given by the Merchant Taylors' Company, in their famous Hall, to the Delegates assembled for the centenary celebrations The function was presided over by the Master. Mr A L F. Cook and the company included as well as a remarkable group of representatives of medicine in all its various branches and of science generally the Lord Mayor of London, the Lord Provost of Glasgow. the Attorney-General, the Minister of Health. the Bishop of Birmingham, Sir William Lister. Sir Edmund Gosse. Sir George Frampton. Lord Chelmsford and Lord Somerleyton After the loyal toasts and the health of the Lord Mayor of London had been drunk the company honoured in silence "the Memory of Lister"

The toast of the Delegates was proposed by Lord Crawford and Balcarres who said that this was a recognition from all parts of the world of Lister's work in physiology and pathology He pointed out that in the general fight against disease the advances that had been made during the lifetime of the Delegates had been vast and progressive. as displayed in the present position of scientific surgery and in what might be called the philosophy of the hospital "We are proud ' said the speaker "to belong to an age in which the relief of human suffering has progressed so marvellously and scientific wisdom been so widely diffused" He wished the physicians and surgeons and pathologists associated with this progress all success

The toast was replied to by Prof J N Nicolaysen and Prof Irving Cameron delegates respectively, from Norway and Canada

Prof Nicolaysen speaking with good command of English expressed the thanks of the Delegates to the Master and Wardens of the Merchant Taylors' Company for their hospitality 'A common feeling he said 'unites all present this evening in most profound respect to the memory of Lister the great son of England whose centenary is being celebrated simultaneously by many of the most venerable institutions in Great Britain Forty years ago I had the great honour and pleasure to be introduced to Sir Joseph Lister (as he then was) and to be present at his operations at King s College Hospital You will understand the feelings of a young surgeon having for the first time an opportunity of seeing at work that hero of his science of whom he had read and heard from the beginning of his medical education. I do not know which I admired more his noble geniality as a man or his thoroughness as an operator This admiration for the great surgeon grew on me as, during the following years I came to learn in a more detailed way of the scientific evolution of his labours; while I was strongly impressed by the fact that Lister's great discovery had been made, not in sudden inspiration, but was the result of close researches made during many years into the determining causes of inflammation and suppuration of wounds And Lister's principles have stood the test His system was taken up in its whole force so to speak during the great war though in a modernised form when a modified aseptic surgery proved insufficient. Magna est veritas et prævalebit."

The toast of the Master of the Merchant Taylors Company was briefly proposed by Sir John Rose Bradford who after testifying to the simplicity of the character of Lister and his tender feelings towards patients and pupils referred to the fact that the Company which was their host had admitted Lister to honorary freedom He said that while the Royal College of Physicians of London made special festival in honour of Harvey. and while the Royal College of Surgeons of England did the same by John Hunter the City of London had, by conferring the Freedom made Lister their own great scientific figure

The proceedings of the dinner were accompanied by an excellent programme of music performed by the band of the Royal Regiment of Artillery and by some delightful singing by the Gresham Singers.

false pride about him. He appreciated all these honours and they were numerous, but they made no difference in his relations with other people or in any way show that he was conscious that he merited any special respect."

Sir **LENTHAL CHEATLE** joined in the welcome to old friends, especially Mr. Hamilton Russell, from Melbourne. He said that Lister was, in every way, the greatest man he had ever met. His great devotion to his work and his courtesy caused all who had dealings with him to revere him. To him a hospital was a sanctuary and he would not endure any infringement of its sanctity. Once, when he had carried out a brilliant operation in 32 seconds, the onlookers cheered him, and Lister's response was to look round and say "Gentlemen, remember where you are." Lister never made inaccurate statements, and he told the speaker one day that he never wished to retract anything he had said or written. The legacy Lister left to mankind, concluded Sir Lenthal Cheatle, would be everlasting, and those who had felt his personal influence would also know that the place filled at his birth and left vacant at his death could never be filled by anybody else.

Colonel R. **BOND**, who came next to Sir Watson Cheyne as Lister's house surgeon, gave many personal reminiscences, and related how he, the speaker, carried the principles into the Sudan campaign and the Boer war.

Mr. **HAMILTON RUSSELL**, of Melbourne, said there had never been to his knowledge any who approached Lister as a dresser; as a dresser at the bedside he was supreme. Every action in Lister's daily life showed that he loved his fellow men; he had the philanthropic temperament, and would point out that when the patient was a child responsibilities were increased.

Mr. **HOWARD P. WARD** spoke of Lister's care in making his own gauze when he discarded his spray and his skill in dressing wounds, which he never tired of doing himself.

Mr. L. **VERNON CARGILL** referred to the care the master inculcated in his students in thinking out every detail of a proposed operation.

Similar tributes were paid by Dr. H. **DISTIN**, Mr. H. **PERRY**, and Dr. A. **BOUSFIELD**.

THE PRIME MINISTER'S RECEPTION

At the reception held in the Great Hall of the British Medical Association on April 5th, the chair was taken by Sir Ernest Rutherford, President of the Royal Society, and delegates from 22 foreign countries and 62 British institutions were received by Mr. Stanley Baldwin, the Prime Minister.

Sir **ERNEST RUTHERFORD** said that it fell to few men in any age to leave behind them such a splendid and permanent memory as Lister had left. It was not necessary to be a specialist to realise what a debt the whole world owed to his discoveries and to his single-minded devotion.

He read congratulatory telegrams from the Imperial Academy of Tokyo and the State Institute of Experimental Medicine at Leningrad.

Mr. **BALDWIN** said that the boundaries of all the nations were broken down in that hall. Only 50 years ago Joseph Lister had come to London to convert his own people. At an International Congress in Amsterdam he had been greeted in words which might well be recalled to mind to-day: "Prof. Lister, it is not only our admiration which we offer you; it is our gratitude and that of the nations to which we belong." These words found their echo years afterwards on the lips of a great American Ambassador who, at a dinner of the Royal Society, said: "My Lord, it is not a profession, it is not a nation, it is humanity itself which with uncovered head salutes you." Such a gathering as this would not have been possible had it not been that in Lister were found all the complementary parts that go to make a man of real greatness. He had been a great master-workman in his own craft; he had brought more relief, more comfort to the human race than almost any man who had lived. But there was also the other side, the man himself. In Lord Lister were those very things which we must admire when we saw humanity raised to its highest point; he was a man truth-loving, truth seeking and truth-living, gentle, filled with charity, a man with never a mean thought. These things were allied to supremacy in his own work.

Lister and France

Prof. **HENRI HARTMANN** (Paris) expressed his pleasure at being appointed to convey the homage of the Académie de Médecine to the memory of Lister, one of its Associate Members. In the middle of the last century Nélaton had written: "A man who came forward with the means of abolishing purulent infection would deserve a statue of gold." French surgeons before Lister—Declat, Lemaire, Maisonneuve and Demarquay—had used carbolic acid in the treatment of wounds, but with indifferent success. Lister had obtained his results because he built up his method on a scientific basis. Prof. Hartmann referred to Lister's practical application of Pasteur's experiments on fermentation, and to Lucas-Championnière's visit to Glasgow in 1868 and his subsequent battle for the establishment of the antiseptic method in France. His friends Berger, Périer, and Terrier had fought the good fight with him and their results had been so striking that soon, as it was said, "Lister was practised throughout France." A veritable revolution in surgery had followed. The discussions of the Société de Chirurgie had entirely changed after 1875; every surgeon had brought before its tribunal his astonishing and novel successes. Surgery continued to evolve; under the vigorous efforts of Terrier, asepsis had been substituted for antisepsis, and less importance was now attached to contamination by germs from the air. Nevertheless, everyone continued to follow the principles which Lister had established; the necessity of putting wounds beyond the power of germs which might contaminate them and the possibility of healing by first intention and of using buried ligatures.

Lister and Germany

Prof. **MAX v. GRUBER** (Munich) said that the greatest successes in the prevention of disease were vaccination introduced by Jenner, the extermination of puerperal fever by Semmelweis, and the antiseptic treatment of wounds by Lister. Lister's work had also an enormous importance to intellectual development, as it was the fruit of theoretical insight. Prof. Gruber said that when a student he had seen what happened daily in an old-fashioned surgical hospital in the era before Lister. Some of the most prominent German surgeons, Bardeleben, Volkmann, and Nussbaum had been among the very first to appreciate to the full the value of antiseptic treatment, and Munich had been the first town to proclaim the immortal glory of Lister and to honour him as one of the greatest benefactors of mankind in 1875. Prof. v. Nussbaum had published a description of the method which according to Lord Lister's own words had contributed more to its rapid victory than any other publication. Under the banner of Lister surgery had made greater conquests within two decades than in two millenniums before. German surgeons had had a glorious share in that triumph. There was not much left of Lister's original methods at present. Many precautions had proved superfluous, others had had to be intensified. But his fundamental perception that wound diseases are infectious diseases had remained unshaken.

Correspondence.

"Audi alteram partem"

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES

To the Editor of THE LANCET

SIR,—There is evidence that what are termed generally philosophic studies would be of advantage to many medical men both by expanding and defining their outlook in relation to general or individual experiences and by affording assistance in the solution of practical difficulties. The need for clear thinking was never more apparent than it is to-day when our expanded range of knowledge adds constantly to a stock of exact information, the bearings of which cannot be confined to any one branch of science but make themselves felt in every field. "What is it all about?" is a question that every well-informed man asks himself when a mental problem, perhaps with a direct reference to action, presents itself to him in a form that is not dictated by his particular equipment. And the more well-informed he is, the more clear will it be to him that he needs fundamental guidance. In other words, he desires help in clear thinking.

The recently-formed British Institute of Philosophical Studies exists in order to afford this help to those who need it. The general object of the Institute is stated thus: "to bring leading exponents of various branches of philosophy into direct contact with the general—ublic with the purpose of satisfying a need, felt by many men and women in every walk of life, for greater clearness and comprehensiveness of vision in human affairs."

Medical men and women are to-day meeting many difficulties that are arising through the vast development of their science—developments of knowledge, of techniques and of administration. these are being accompanied by a broadening of view in their ranks, and also by a multiplication of the relations of medicine to society brought about by far-reaching changes in the law. The position must therefore often arise when medical men or women need clearness and comprehensiveness of vision. They would benefit by an opportunity of taking counsel with those in other sections of activity, who may be meeting their own problems from a different angle or who may be able to give an opinion on medical problems which gains in breadth and public influence from its detachment from medicine. Further medicine by cooperation can confer on those other sections of activity the advantages of sharing considered medical opinion and of learning the arguments relied upon for its establishment.

Sociological and psychological questions arise constantly out of all medical practice, and not only out of those sides of medical practice apparently concerned with mental disease or moral conduct, while metaphysics must play a part in any comprehensive attempt to distinguish between normal and abnormal conditions physical or mental—indeed between health and disease. A general philosophical equipment will be of great use to the practitioner as a supplement to all detailed scientific knowledge, for it will conduce to clear thinking.

For these reasons we advocate the claims on members of the profession of the British Institute of Philosophical Studies the temporary offices of which are at 88, Kingsway. The Hon. Secretary would be glad to give any information desired. The subscription payable by members of the Institute is only £1 1s. per annum.

We are, Sir, yours faithfully,

(Sgd.) DAWSON OF PENN THOMAS HORDER

TESTS FOR DRUNKENNESS

To the Editor of THE LANCET

SIR,—A great deal of interest has been aroused in the question of the insobriety of motor-drivers by numerous police-court cases which have been commented on in the press, and have often been the subject of conflicting evidence and appeals. Recently the British Medical Association appointed a Committee to inquire into the tests for drunkenness. Their results have now been published.[1]

The Committee's recommendation for a new legal definition of drunkenness is one which will be commended by all who recognise that a man need not be grossly intoxicated by alcohol to render him unfit to be in charge of a car. This point was stressed in a pamphlet published early in 1926 by The True Temperance Scientific Committee, under the title, "The Problem of the Intoxicated Motor-Driver."

Coming now to the tests for drunkenness which the Committee favour, one doubts whether commendation will be as uniform for of the various tests suggested. foremost rank is given to the test of smelling alcohol in the breath or vomit, than which one ventures to suggest, a more unscientific test could not be found for the following reasons:

1. The concentration of alcohol in the exhaled breath is much more a function of the *rate* of blood supply to the lungs than it is to the concentration of alcohol in the blood. Consequently an accused, intoxicated to the stage of restlessness may through his active movements be actually exhaling breath containing a greater concentration of alcohol than one dead drunk whose respirations are slow and shallow.

2. The application of the sense of smell is an uncertain method of analysis. Not only does this sense vary enormously between individuals but also in the same individual. The effect of a cold on the sense of smell is a by-word. Also one wonders how the examining police surgeon's olfactory sense will react if he himself has had alcohol previously with his dinner? The Committee naively point out that the success of the olfactory method of diagnosis depends on the keenness of the sense of smell of the individual applying the test!

One ventures to think that the Report is an unhappy effort to deal with the subject. It is a step backwards, for to urge the usefulness of the sense of smell in this connexion means nothing else. That senior police surgeons many of whom are quite satisfied with the present day tests for drunkenness should favour this particular test, is not surprising, but that an analytical chemist and toxicologist of Sir William Willcox's standing should also subscribe to it is beyond one's comprehension.

This is a subject in which the present writer is keenly interested, because he has been carrying out experimental work during the past four years which bears directly on this difficult problem. Some results of this work were embodied in a paper by Drs. Southgate and Carter,[2] who showed that from an analysis of the alcohol in the urine not only could the concentration of alcohol in the blood (the best index of intoxication) be deduced, but also a close approximation of the least amount of alcohol which had been drunk. The British Medical Association Committee, whilst acknowledging the great value of this work from a scientific point of view, maintain that tests depending on the examination of the urine are not practicable. Why it is not practicable to examine the urine is not stated. Is the difficulty a legal one? One cannot conceive why the police surgeon has a right to examine the excretions from the lungs or a return from the stomach and yet none to analyse the excretions from the kidneys. The impracticability cannot depend on difficulty of analysis, for an accurate analysis of alcohol in the urine can be carried out by any competent analytical chemist in half an hour.

MEMORIAL SERVICE IN WESTMINSTER ABBEY

On Wednesday morning, April 6th, the centenary of Lord Lister's birth was commemorated by a service in Westminster Abbey, where he would have been buried but for his expressed wish The large congregation was representative both of the sciences which his discoveries enriched and of the public which they served The service opened with Addison's hymn, "The Spacious Firmament on High," and after the chanting of the eighth Psalm, the lesson was read from St Luke vii (verses 19–23) The choir then sang Handel's anthem

> When the ear heard him, then it blessed him and when the eye saw him it gave witness of him He delivered the poor that cried the fatherless and him that had gone to help him Kindness, meekness and comfort were in his tongue If there was any virtue, and if there was any praise, he thought on these things His body is buried in peace, but his name liveth evermore

This anthem was the one sung at the memorial service to Lord Lister at the Abbey in 1912

An address was then given by the Bishop of Birmingham, the Rt Rev E W Barnes, F R S, who called attention to Lister's personal qualities, to the religious principles which guided his actions, to the patient enthusiasm which served his genius, and to the inestimable value of his life-work Lister belonged to that group of men whose achievements gave them a secure place in the history of civilisation Throughout his life his work bore the stamp of humility, in a word, he possessed the true scientific spirit with the insight of genius Praise and success in no way spoiled him, and in nothing did he show himself unworthy of the respect he had gained

Whether through Lister's work discoveries of equal importance would be made in the future—whether we should be able to prevent the onset of disease, it was impossible to say, but there need be no hesitation in affirming that further triumphs in the warfare against disease would surpass the victories already won, for the achievements of the leaders of human progress gave substance to our hopes Lister's single-minded devotion to science would inspire others to work for the welfare of the human race

The service closed with the hymn, "Now thank we all our God"

THE CENTENARY AT GLASGOW

The celebrations at Glasgow were held on April 1st They began with a commemoration service in the Cathedral, to which the clergy, corporation, and academic representatives and delegates walked in procession Sir Donald MacAlister, Principal of the University, read the first lesson and the commemoration address was given by the Rev McLean Watt, Minister of the Cathedral

A civic luncheon followed, at which the Lord Provost presided and Sir John Bland-Sutton proposed the toast of "The Illustrious Memory of Lord Lister" (His speech appears on p 781 of this issue of THE LANCET) A second toast, "The Medical School of Glasgow," was given by Dr A Logan Turner, President of the Royal College of Surgeons of Edinburgh, who referred to Lord Lister's memory as a link between the Glasgow and Edinburgh Schools at which he worked Sir Donald MacAlister spoke of the origin of antiseptic surgery at Glasgow, and Dr R M Buchanan, President of the Royal Faculty of Physicians and Surgeons of Glasgow, giving the toast of "The Glasgow Corporation," referred to the application of Lister's principles to public health

In the afternoon many representatives visited Kelvingrove Park and laid wreaths at the foot of the Lister Monument In the evening there was a reception in the Bute Hall of the University, where Sir Donald MacAlister welcomed the guests and Sir Hector Cameron and Sir George Beatson recalled the character of Lord Lister's work as they had seen it Other addresses were given by Prof Irving, H Cameron (representing the Royal Society of Canada), and Prof Murdoch Cameron, the proceedings ending with a vote of thanks to the speakers, proposed by Prof Archibald Young, who occupies the Regius Chair of Surgery in the University of Glasgow Amongst those who attended the celebrations was Dr W G Stevens, of Renfrew, who was present when Lister performed the first operation at which he observed antiseptic rules

DISTRICT NURSING IN LONDON—The main work of the Central Council for District Nursing in London last year lay in consolidating the nursing of London itself and in extending the service on the outer borders of the county A new association was established at Eltham Hill on provident lines, and there has been considerable extension of work in Middlesex The places where nurses are most obviously needed are the growing areas on the outskirts of London Unfortunately the Council find that its invested funds are practically exhausted and, unless some new source of income can be found, the annual grants will have to be cut down severely It is to be hoped that some way out may be revealed, as the value of the district nurse to the practitioner is only rivalled by her significance as a factor in public health and the prevention of disease and King regarding the anæsthetic properties of pure ether, he stated that of all the commercial ethers which he had examined none was chemically pure. He then described a method which he had evolved for preparing an absolutely pure ether, which consisted of a process by which ether was made to combine with benzidine to form a crystallised double salt. This double salt could be readily purified, and after purification decomposed into its component parts. The ether made in this way was absolutely pure, and, unlike all the commercial ethers which Prof. van Leeuwen had examined, was perfectly stable. It was established also that absolutely pure ether could not be made by redistillation alone, but that a chemical method also was necessary.

A few months later a paper was read at the British Pharmaceutical Conference by G. Middleton[5] of the laboratories of The British Drug Houses Ltd., and in this paper a delicate test for the detection and quantitative estimation of peroxides present in anæsthetic ether was described. The paper contained also, a report on the determination of the stability of various ethers, and from the data given it was observed that ether purified from aldehyde is much less prone to oxidation and to the formation of peroxides than any ether not so purified. Following these researches it came to be more clearly recognised that the presence of impurities in ether causes deleterious effects after administration, and more recently several investigators have provided additional evidence of this view. For instance, J. Mita[6] has demonstrated experimentally what had been repeatedly indicated as a result of the general observations of anæsthetists and others that the toxicity which develops in ether increases proportionately to the degree of oxidation by exposure to light and air; and he showed that oxidised ether in addition to producing local and necrosing effects had very distinct actions on the heart and the central nervous system. He attributed these toxic phenomena to the peroxides first obtained from ether by Wieland.

In October, 1926, the Anæsthetic Committee appointed by the Royal Society of Medicine issued an interim report in which it was stated that "the purer the ether the better the anæsthetic." Also in a paper read before the anæsthetic section at the recent annual meeting of the British Medical Association Dr. F. H. McMechan[7] said:

> "Certain impurities in anæsthetics may merely involve disagreeable odours or tastes; others may be responsible for nausea and vomiting, while still others may induce pathological conditions leading to endangering complications or even death. As most of these are effective when present in traces represented by percentages in the second to the fourth decimal places, their absolute elimination is imperative."

It was clearly the duty of manufacturers to act in accordance with this new knowledge as to the importance of purity in anæsthetic ether, and one of them in particular, The British Drug Houses Ltd., introduced a more highly purified ether, free from all traces of aldehyde and peroxide. This pure ether is packed and issued in light-proof packings under conditions which preclude the possibility of the formation of peroxide, thus permitting its arrival in the operating room in a perfectly pure condition.

The importance of the light-proof packing is due to the fact that, while pure ether is very much more stable to light than less pure ether, it undergoes very gradual change if allowed to stand in the light. If to a bottle of pure ether there is added some stale ether which has been exposed to light, the whole quantity will be rendered unstable. When using the closed method of administration (Shipway) oxygen or air is bubbled through ether in a bottle which is usually of colourless glass. Consequently during the administration impurities are formed in the apparatus. If the practice is followed of adding fresh ether to the surplus left over from the previous operation there accumulates in the apparatus a highly concentrated solution of impurities. Each addition of pure ether therefore merely dilutes this solution: with the result that what is administered to the patient is an impure mixture. The longer the surplus ether is allowed to accumulate in the apparatus the worse is the effect. It is important, therefore, that this residual ether should be thrown away after each operation, so that any fresh ether transferred to the apparatus may not become harmfully contaminated. For the same reason the contents of the apparatus should not be mixed with any ether which is likely to be subsequently used for anæsthetic purposes.

Very little extra expense is involved in taking these precautions; indeed highly purified ether is now made on such a large scale that the makers have reduced the price to about the same as that of other ethers: at the same time it should be emphasised that the advantages resulting from the absence of toxic effects far outweigh any possible considerations of price. Dr. Waldo has done a great public service in directing attention to the dangers resulting from the use of impure ether, and his suggestion that an analyst's certificate of purity should accompany all anæsthetic ether should be strongly supported by enlightened opinion with the object of securing its legal enforcement.—I am, Sir, yours faithfully,

April 2nd, 1927. H. E. LAWS.

OPHTHALMIC BENEFIT.

To the Editor of THE LANCET.

SIR,—I was simply astounded at Mr. Caddy's letter, and must express my full agreement with the replies from Mr. Lumsden and "F.R.C.S. Oculist." Allow me to point out a few fallacies in the working of this scheme. Previous to the adoption of ophthalmic benefit the approved societies were accustomed to pay the opticians a testing-fee of 5s. or more, and some of the societies continue to do so for every insured patient. May I ask why this fee is necessary when no optician demands this fee from the public?

In spite of the doctor recommending that his patient should be examined by an ophthalmic surgeon some societies send the patient direct to the opticians. To my mind this shows a disregard for the patient's sight and is insulting to the doctor. I think I am right in stating that it is intended that the doctor (and not the optician) who is expected to decide as to what cases should go to the ophthalmic surgeons. In my opinion the doctor is placed in an extremely difficult position and the responsibility is too great. Mr. Caddy seems to think it is enough to pick out the cataract, new growth, and glaucoma cases. My extensive out-patients' experience has taught me that a fair percentage of really serious medical cases attend all ophthalmic clinics. Let me mention a few types—e.g., patients suffering from arterio-sclerosis, diabetes, renal disease, hemianopia, retinal hæmorrhage, encephalitis lethargica, optic neuritis, &c. In a proportion of these cases it is surprising how little the visual acuity is affected, and the doctors were not aware of the condition at the time. It was the ophthalmic surgeon who had diagnosed the actual disease. If this is so, here we have a large number of serious cases not recognised by trained medical men. Surely, then, a tradesman with no medical training is less likely to recognise these cases and appreciate their seriousness.

If I were an optician I should hardly like to assume such grave responsibility. One's sight is much too precious, and although 5 per cent. (I think it is more like 20 per cent.) of the cases are involved and because these are panel patients, I think it is criminal to jeopardise the sight of even 1 per cent. of this total.

It will be detrimental to the public interests to have opticians meddling with the work of the ophthalmic surgeons and vice versa. Remember we do not sell glasses, and all prescriptions for glasses go back to the opticians. Why do they seek for this

[6] J. Mita: Jour. de Pharm. et Chem., 1926, iii, [illegible]
[7] F. H. McMechan: Brit. Med. Jour., 1926, ii, 1106.

In their paper, the two authors referred to only asked that the results of their work should be corroborated by others This the British Medical Association committee has denied them If this committee had organised a similar set of tests on the human subject and compared the results of the amount of alcohol drunk, the resulting concentrations of alcohol in the blood and urine, with the toxic symptoms produced, one ventures to think they would agree that anyone, whether accustomed or not to alcohol, with a blood alcohol concentration of 200 mg per 100 grammes of blood, corresponding to about 260 mg in the urine is quite unfit to be in charge of a motor-car

THE PENALISATION OF THE TUBERCULOUS

To the Editor of The Lancet

Sir,—The letters which have appeared lately under this heading are of such great human interest, especially that of " Eradication," that I feel bound to crave space for a few words on this unusual view-point of after-care They express sentiments which go deep down into the well of human nature They fathom the deeps of Life's ocean It is the cry of the wounded to be given a chance , a cry, not for charity, but for work It is almost a universal cry In these two letters we hear it from members of the medical profession This is not usual If we listen we may hear it from members of other professions, from members of the legal profession, from nurses and teachers The cry increases as the economic strain becomes greater, until from the black-coated clerk and those beyond the dole, it becomes the cry of the multitude And the cry is incessant

Those of us who are employed in the tuberculosis field but who are not ourselves sufferers cannot fail to have been struck with the seriousness of the question which " Eradication " addresses to you, Sir " And if they are debarred from getting employment, what is the use of treating them ? " and if we have no answer to that question, what is our position ? How are we to answer the question " If tuberculosis authorities will not employ their ex patients, who can be expected to do so ? "

From one who has had the misfortune to contract the disease, and who has had the still greater misfortune to be denied employment as a sanatorium physician, the cry " What is the good of treating them ? " comes as a poignant appeal We feel he is our own kith and kin To be turned down for a job—the grossest penalisation But it is happening every day to a far greater extent amongst all those who do not belong to the medical profession We hear little of the penalisation in such cases Why ? Because, as a profession, we have never answered, indeed, never faced the question fairly " And if they are debarred from getting employment, what is the use of treating them ? " Medical men who have suffered from pulmonary tuberculosis have in many cases as " Eradication " points out, found in sanatorium work an environment in which their work can be made to suit their damaged condition They have as I have pointed out elsewhere, found an equilibrium But it by no means follows that the work in every institution is light enough for the damaged organ It emphatically is not in many cases, for breakdowns are frequent, and, indeed, deaths are not unknown

But it is not my present object to discuss whether a tuberculous medical man is the ideal medical officer for a sanatorium Faith in the cure may not be entirely lacking in the healthy, however depressing sanatorium statistics may be But of far greater importance is the determination to see that " if tuberculosis authorities will not employ their ex-patients " *then someone else will*, and that " if they are debarred from getting employment (even as a medical man in a sanatorium), they shall be found remunerative employment in an environment best suited to their condition Such an environment I saw last summer at Saranac Lake, such employment for medical men which makes it impossible to speak of the penalisation of the tuberculous, and I look forward to the time when Papworth will provide similar opportunities When we can answer the question " What is the use of treating them ? ", when we can be quite sure that we have the right answer, and not the half-answers usually given, then, and only then, will the penalisation of the tuberculous cease

" Eradication " is too modest Not only should tuberculous medical men combine in an attempt to " cure themselves with an appointment," but they should see to it that all those who have taken the trouble to get well combine also Let us attempt to make it possible for all who have taken the trouble to get well to cure themselves with an appointment—in other words, provide efficient after-care

" To cure ourselves with an appointment " should, indeed, be the slogan of the future for the tuberculous

I am, Sir, yours faithfully,

P. C Varrier-Jones

Papworth Hall, Cambridge, March 28th, 1927

ANÆSTHETIC ETHER

To the Editor of The Lancet

Sir,—The recent remarks by the Southwark coroner Dr F J Waldo, on the desirability of the use of absolutely pure ether for the production of anæsthesia has focused attention again on this important matter, and a review of the position at this stage seems to us to be indicated

Some ten years ago the necessity for purity in ether formed the subject of a controversy which lasted over a period of years It started in 1917 with a claim made by J H Cotton [1] that by the purification of ether he had deprived it of its anæsthetic properties In view of this he attributed the anæsthetic properties of ordinary ether to the presence of ethylene and carbon dioxide Four years later Wallis and Hewer,[2] implied that they, also, had found that pure ether possessed no anæsthetic properties, adding that its function was that of a vehicle for the " anæsthetic compound," the principal constituents of which were certain ketones As a result of this they advocated the addition of ketones to ordinary ether to increase its anæsthetic properties This remarkable publication led to a careful investigation by several workers of the anæsthetic action of ether, and to a study of the physiological action of the impurities which are commonly found in commercial ethers

In a paper published in 1923 Dale, Hadfield and King [3] disposed conclusively of the view that perfectly pure ether was not a good anæsthetic These workers prepared a quantity of ether and purified it by repeated fractionation, washing it with caustic soda and water, boiling with potassium permanganate refractionating, and drying first by calcium chloride and then by metallic sodium and refractionating again By this long and careful process of purification they prepared an ether which distilled between 34 1° C and 34 15° C at 751 mm This ether they regarded as free from aldehydes, ketones acids, mercaptans, alcohol and all other known impurities, including ethylene The pure ether was then tested on animals by Dr Dale, and on human beings by Dr Hadfield, and the results proved that it was in every way a perfectly satisfactory anæsthetic The ketone theory was reduced to an absurdity by this careful and authoritative work

The next step taken was to investigate the physiological action of impurities in anæsthetic ether, and in March, 1924, Prof Storm van Leeuwen [4] of Leyden read a paper before the Anæsthetic Section of the Royal Society of Medicine (in London) in which, in addition to confirming the opinion of Dale, Hadfield and King regarding the anæsthetic properties of pure ether, he stated that of all the commercial ethers which he had examined none was chemically pure. He then described a method which he had evolved for preparing an absolutely pure ether which consisted of a process by which ether was made to combine with benzidine to form a crystallised double salt. This double salt could be readily purified, and after purification decomposed into its component parts. The ether made in this way was absolutely pure, and, unlike all the commercial ethers which Prof. van Leeuwen had examined, was perfectly stable. It was established also that absolutely pure ether could not be made by redistillation alone, but that a chemical method also was necessary.

[3] H H Dale C F Hadfield and H King Ibid 1923, i, 424

[4] Storm van Leeuwen Ibid, 1924, i, 561

A few months later a paper was read at the British Pharmaceutical Conference by G. Middleton,[5] of the laboratories of The British Drug Houses Ltd., and in this paper a delicate test for the detection and quantitative estimation of peroxides present in anæsthetic ether was described. The paper contained also, a report on the determination of the stability of various ethers, and from the data given it was observed that ether purified from aldehyde is much less prone to oxidation and to the formation of peroxides than any ether not so purified. Following these researches it came to be more clearly recognised that the presence of impurities in ether causes deleterious effects after administration and more recently, several investigators have provided additional evidence of this view. For instance, J. Mita[6] has demonstrated experimentally what had been repeatedly indicated as a result of the general observations of anæsthetists and others, that the toxicity which develops in ether increases proportionately to the degree of oxidation by exposure to light and air; and he showed that oxidised ether, in addition to producing local and necrosing effects had very distinct actions on the heart and the central nervous system. He attributed these toxic phenomena to the peroxides first obtained from ether by Wieland.

In October 1926, the Anæsthetic Committee appointed by the Royal Society of Medicine issued an interim report in which it was stated that "the purer the ether the better the anæsthetic." Also, in a paper read before the anæsthetic section at the recent annual meeting of the British Medical Association Dr. F. H. McMechan[7] said:

> "Certain impurities in anæsthetics may merely involve disagreeable odours or tastes, others may be responsible for nausea and vomiting, while still others may induce pathological conditions leading to endangering complications or even death. As most of these are effective when present in traces represented by percentages in the second to the fourth decimal places, their absolute elimination is imperative."

It was clearly the duty of manufacturers to act in accordance with this new knowledge as to the importance of purity in anæsthetic ether, and one of them in particular, The British Drug Houses Ltd., introduced a more highly purified ether free from all traces of aldehyde and peroxide. This pure ether is packed and issued in light-proof packings under conditions which preclude the possibility of the formation of peroxide, thus permitting its arrival in the operating room in a perfectly pure condition.

The importance of the light-proof packing is due to the fact that while pure ether is very much more stable to light than less pure ether it undergoes very gradual change if allowed to stand in the light. If to a bottle of pure ether there is added some stale ether which has been exposed to light the whole quantity will be rendered unstable. When using the closed method of administration (Shipway) oxygen or air is bubbled through ether in a bottle which is usually of colourless glass. Consequently during the administration impurities are formed in the apparatus. If the practice is followed of adding fresh ether to the surplus left over from the previous operation there accumulates in the apparatus a highly concentrated solution of impurities. Each addition of pure ether therefore, merely dilutes this solution; with the result that what is administered to the patient is an impure mixture. The longer the surplus ether is allowed to accumulate in the apparatus the worse is the effect. It is important, therefore that this residual ether should be thrown away after each operation, so that any fresh ether transferred to the apparatus may not become harmfully contaminated. For the same reason the contents of the apparatus should not be mixed with any ether which is likely to be subsequently used for anæsthetic purposes.

Very little extra expense is involved in taking these precautions; indeed highly purified ether is now made on such a large scale that the makers have reduced the price to about the same as that of other ethers, at the same time it should be emphasised that the advantages resulting from the absence of toxic effects far outweigh any possible considerations of price. Dr. Waldo has done a great public service in directing attention to the dangers resulting from the use of impure ether, and his suggestion that an analyst's certificate of purity should accompany all anæsthetic ether should be strongly supported by enlightened opinion with the object of securing its legal enforcement.—I am, Sir, yours faithfully,

April 2nd, 1927. H. E. LAWS.

OPHTHALMIC BENEFIT

To the Editor of THE LANCET

SIR,—I was simply astounded at Mr. Caddy's letter, and must express my full agreement with the replies from Mr. Lumsden and "F.R.C.S. Oculist." Allow me to point out a few fallacies in the working of this scheme. Previous to the adoption of ophthalmic benefit the approved societies were accustomed to pay the opticians a testing-fee of 5s. or more and some of the societies continue to do so for every insured patient. May I ask why this fee is necessary when no optician demands this fee from the public?

In spite of the doctor recommending that his patient should be examined by an ophthalmic surgeon some societies send the patient direct to the opticians. To my mind this shows a disregard for the patient's sight and is insulting to the doctor. I think I am right in stating that it is intended that the doctor (and not the optician) who is expected to decide as to what cases should go to the ophthalmic surgeons. In my opinion the doctor is placed in an extremely difficult position and the responsibility is too great. Mr. Caddy seems to think it is enough to pick out the cataract, new growth, and glaucoma cases. My extensive out-patients' experience has taught me that a fair percentage of really serious medical cases attend all ophthalmic clinics. Let me mention a few types—e.g., patients suffering from arterio-sclerosis, diabetes, renal disease, hemianopia, retinal hæmorrhage, *encephalitis lethargica*, optic neuritis, &c. In a proportion of these cases it is surprising how little the visual acuity is affected, and the doctors were not aware of the condition at the time. It was the ophthalmic surgeon who had diagnosed the actual disease. If this is so, here we have a large number of serious cases not recognised by trained medical men. Surely, then, a tradesman with no medical training is less likely to recognise these cases and appreciate their seriousness.

If I were an optician I should hardly like to assume such grave responsibility. One's sight is much too precious, and although 5 per cent. (I think it is more like 20 per cent.) of the cases are involved and because these are panel patients, I think it is *criminal* to jeopardise the sight of even 1 per cent. of this total.

It will be detrimental to the public interests to have opticians meddling with the work of the ophthalmic surgeons and vice versa. Remember we do not sell glasses, and all prescriptions for glasses go back to the *opticians*. Why do they seek for this extra and grave responsibility? Have we not all had experience of patients being sold two or three pairs of glasses when only one pair or none was necessary? Similarly, there is the wholesale abuse of forcing the public to buy Crookes's lenses. No, the optician should only dispense our prescriptions and sell other optical goods, and this is the only safeguard for the public. No one denies that there are opticians who are competent to do refraction cases. But I should like the majority to concentrate on *dispensing a prescription accurately and on fitting the frames correctly*. This is their job, and it is really surprising how few know it apart from the class of dispensing opticians. It is quite true the bulk of an ophthalmic surgeon's work is to prescribe glasses, and it is the same for private and hospital work. If 80 per cent. of the work—i.e., refractions of panel patients are referred to the opticians according to Mr. Caddy's wish—I wonder if he will also send similar cases in private to the opticians and only deal with those suffering from ocular diseases. If the public can afford our fees they will do so every time, and I need not state the reasons for it. Why should not the panel patient be accorded the same privileges if his society can afford a reduced fee?

The only sound way to deal with every eye case, whether private or panel, is for the doctor to send such cases direct to an ophthalmic surgeon, who will assume full responsibility. Sight is much too precious to be tampered with by unqualified men, and even the ophthalmic surgeon finds it difficult sometimes to make a diagnosis. Ophthalmic benefit is for panel patients who are free to choose their doctors; similarly, they must be allowed to choose their ophthalmic surgeons. Let us not depart from this principle.

I am, Sir, yours faithfully,
J. MYLES BICKERTON, B.Ch. Camb., F.R.C.S. Eng.,
Dean of Royal Eye Hospital.
London, W., March 29th, 1927.

To the Editor of THE LANCET.

SIR,—Dealing with the various points raised in the last letter (the only unsigned one) under this heading in your issue of April 2nd, may I say that from my own experience of the Acts that have been passed in the 47 States of America, in Canada, and in Australasia, and based upon authoritative information, such legislation has proved to the benefit of the spectacle-wearing public and of those who have diseases of the eye which would have remained undetected but for the findings of the skilled optician.

Secondly, it is not true that the various optical organisations are on terms of bitter enmity. There are only two recognised examining bodies in England, the Spectacle Makers' Company and the British Optical Association, and they work in perfect friendship with each other. Although there are only these two recognised bodies, there are other important bodies of opticians, such as the National Council for the Preservation of Eyesight, the Institute of Ophthalmic Opticians, and the Association of Wholesale Manufacturing Opticians, all of which work in perfect harmony with each other. As is inevitable, not only with unregistered professions, but even with State recognised callings, there are springing up, especially in view of imminent legislation, mushroom societies, and certificates which may be bought with little trouble. It is but natural that such new societies should be at variance with the others, and plead from time to time in the press for equality and broad-mindedness. It is the obvious view-point of an individual without property on the question of equal division of property. The Joint Council of Qualified Opticians is a body with a special licence from the Board of Trade to dispense with the word "Limited," on account of its not giving any profit to its members, and because it is a body formed for a scientific or charitable purpose. It could not be described as a limited company. The entrance fee to the J.C.Q.O. for a qualified optician is nominal—only 5s. It is not correct to state that any further percentage beyond the ordinary two-and-a-half per cent. for ordinary administrative expenses is deducted. The J.C.Q.O. has nothing whatever to do with any eagle or any advertisement, and your correspondent is confusing this society with another body.

Thirdly, the nominal testing fee of 5s. is allowed to an optician in all cases where he finds glasses are not required, and it is this very allowance in such cases, and the severe ethical discipline exercised over its members, that induced the major Approved Societies at its inception to place their work unreservedly through the clearing-house of the J.C.Q.O.

Fourthly, the optician does not advertise or prescribe spectacles to the public as a "cure-all." I am quite certain that if such an advertisement came before the notice of my Executive, the perpetrator would be immediately hauled up for infringement of its code of ethics.

Fifthly, with regard to a very serious charge that your anonymous correspondent makes, that relating to the mistakes of opticians, he is generalising from three of his own cases. Within a week ago, anticipating similar unsportsmanlike attacks, I wrote to our members of the J.C.Q.O. asking them to give me any evidence that they could at short notice in the following clauses: 1. Evidence of errors in diagnosis by medical men. 2. Cases of patients requiring ordinary lenses being specially referred by medical practitioners to ophthalmic surgeons. 3. Evidence to shew that medical men are referring cases to them as optical practitioners. Within two posts I received over 200 bulky envelopes in reply to my request. The task of sorting these is obviously going to be so great that I have not even opened the envelopes. But your correspondent may find that the unsportsmanlike attitude he adopts will only come back as a very powerful boomerang.

Sixthly, your correspondent says that the average optician devotes too much attention to the commercial side, and in contrast mentions the Association of Dispensing Opticians. But the members of this body, for which I have every respect and esteem, do not test sight, and therefore, as is but right, their businesses are purely commercial, with every desire to give good value and service for money, but still commercial.

Lastly, your correspondent makes the absurd statement that anyone can acquire sufficient knowledge in ten hours to call himself a fully qualified optician. I am enclosing the syllabus of our B.O.A. Examinations, where you will see a curriculum such as will *take an average intelligent man from two to three years to prepare for*.

One realises that there are two sides to a question, and that each side may think it is right; but one would like to see such a campaign carried on with regard to truth and with an absence of personalities.

I am, Sir, yours faithfully,
J. H. SUTCLIFFE,
Registrar of the Joint Council of Qualified Opticians,
Secretary of the British Optical Association.
Clifford's Inn Hall, Fleet-street, E.C., April 2nd, 1927.

To the Editor of THE LANCET.

SIR,—In the letter signed "Ophthalmic Surgeon," which appears on page 729 of your last issue, there is a reference to the Joint Council of Qualified Opticians, in which the statement occurs that "the insurance companies allow a testing fee of 5s. to the optician for every case for which spectacles are supplied." Evidently the writer is not familiar with the facts, as the consultation fee of 5s. is paid in every case where the patient is examined by the optician whether the patient is referred for medical advice or not, and has no relation whatever to the supply of spectacles.—I am, Sir, yours faithfully,

F. T. GREGG,
Secretary, Institute of Ophthalmic Opticians.
Bank Chambers, High Holborn, W.C., April 2nd, 1927.

Public Health Services.

SCHOOL MEDICAL SERVICE

AMONG the first annual reports to be presented are those of Ilford, Taunton, and Torquay. Some of the statistical details of these are indicated below.

Name of district	No. on roll.	Av. elem. school attendance	No. of routine children examined.	No. of special examinations and re-inspections	Percentage of children found on routine examination requiring treatment *
Torquay	3,775	3,371	1,274	5,510	19.0
Taunton	2,909	2,681	1,038	2,936	26.8
Ilford	13,144	—†	5,658	8,964	42.1

* Excluding uncleanliness and dental defects. † Not given.

Torquay

The school medical officer, Dr. T. Dunlop, in his introduction, is able to say that there is no child in the Torquay schools with defective vision untreated and that practically all spectacles prescribed have been obtained and made use of. Dr. J. V. A. Simpson points out in his detailed report that this ophthalmic work, like the other treatment facilities of the school clinic, is available for children of pre-school age. The chief factors which produce defects in school entrants are thus stated: (1) Irregular feeding, (2) irregular hours of sleep, (3) infectious diseases. An account is given of the open-air school which is not regarded as "merely a school in the open air." An appendix contains a further series of Dr. Simpson's observations with the kata-thermometer, the time taken to fall from 100° F. to 95° F. is taken as a measure of the cooling and evaporative powers of the air. According to Dr. J. Kerr this instrument "has added enormously to the power of examining the air in respect of ventilation as it integrates all effects, positive and negative, giving a result concordant with the ventilation effects on the body." Dr. Leonard Hill's minima of 6 for the dry and 18 for the wet reading are regarded by Dr. Simpson as too low; he would prefer the figures of 7 and 20 respectively. The detailed figures he gives do not in general reach this high standard; they do indicate, however, that though the buildings may not be ideal, the ventilation is, on the whole satisfactory. In several of the best examples there is a comment "open fires," and in one of the worst "window shut, cord broken."

Taunton

Dr. John Allen, in his eighth annual report, notes with pleasure the supersession of the antiquated long desk by the new single type, but deplores the retention of some insanitary latrines. Although in some cases the attendance has fallen below 60 per cent., owing to mumps and German measles, no school or department has been closed. There has been a rapid rise in the percentage of children requiring treatment—from 10.1 per cent. in 1924 to 26.6 per cent. in 1926—due, of course, to an all-round raising of the standards. Supervision of pre-school children is included in the maternity and child welfare scheme and the records are available for the school medical officer. The orthopædic scheme in conjunction with the Somerset County Council is now working well, and a strong voluntary committee is providing useful help; 2.1 per cent. of the children were classed as cripples and found to be in need of this treatment. This percentage is considerably in excess of the average for England and Wales, but it should be borne in mind that the initiation of a scheme implies a careful look-out for every child in need of orthopædic treatment. The Somerset Association for Mental Welfare have an occupation centre for low grade defectives which is held in the rooms of the local Y.M.C.A. and is open three days a week.

Ilford

With the rapid growth of the population at Ilford and the inclusion of Dr. Barnardo's Mossford School for Girls under the direct control of the local education authority, many more school-children were examined during 1926 than in former years. Dr. A. H. G. Burton regrets that the open-air school, the site of which was approved by the Board of Education in 1924 is not yet in being, nor is there as yet any special provision for mentally or physically defective children. Two interesting tables are given comparing the incidence-rate per 1000 of crippled and defective children in Ilford with that for the country as a whole. The figure for crippled children in Ilford is 1.7 against 10.0 for England and Wales. The Ilford analysis, however, includes only those children who are so physically defective as to be unable to attend school, or who should be in attendance at a special school. This way of stating the figures is misleading in that it tends to lessen the apparent urgency for special provision for such children; it is in the minor and progressive cases that special treatment is most called for and on which attention should be focused. Were he to give the total numbers Dr. Burton would strengthen his urgent request for a remedial clinic for minor defects; in the meantime all minor deformities receive special attention from the supervising instructor in physical training. The high standard of visual acuity demanded is shown by the incidence-rate per 1000 of visual defects in Ilford, 77.0 against 54.7 for England and Wales. All minor defects even in those reading 6/6 Snellen's type are referred to the oculist. The standards adopted for operative treatment for adenoids are "chronic nasal obstruction or where adenoids can be felt digitally." For tonsils "where this condition has been keeping up such defects as otorrhœa, deafness, and frequent attacks of tonsillitis." Statistical tables show the heights and weights of Ilford children compared with the anthropometric standards, and also the school incidence of infectious diseases.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 26TH, 1927

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 404 (last week 442); scarlet fever, 1292; diphtheria, 974; enteric fever, 54; pneumonia, 1373; puerperal fever, 39; puerperal pyrexia, 109; cerebro-spinal fever, 13; acute poliomyelitis, 5; acute polio-encephalitis, 1; encephalitis lethargica, 37; dysentery, 15; ophthalmia neonatorum, 146. No case of cholera, plague, or typhus fever was notified during the week.

Deaths.—In the aggregate of great towns, including London, there was one death from small-pox, 1 (0), from enteric fever, 71 (2), from measles, 6 (2), from scarlet fever, 89 (22) from whooping-cough, 35 (11), from diphtheria, 51 (16) from diarrhœa and enteritis under two years, and 224 (33) from influenza. The figures in parentheses are those for London itself. The death from small-pox was registered in Sheffield C.B.

BIRMINGHAM HOSPITALS.—According to the annual report of the Queen's Hospital, the new extension will be completed in a few weeks and, very little later, when the present surgical block has been renovated, the hospital will have added nearly 100 new beds to its normal establishment, thus reducing the serious scarcity of beds in the city.—Although it contains only 116 beds the Women's Hospital and Maternity Hospital last year dealt with the "record" number of 2443 in-patients. The average daily cost per patient was 9*s.* 6*d.* Extensive antenatal work is also being done.—The Birmingham Hospital Saturday Fund likewise achieved a "record" by raising over £65,000 last year. The great increase in applications for convalescent treatment, especially for men, is compelling the enlargement of the Tyn-y-Coed Home by the addition of 60 beds, which will bring up the number to 125.

Special Articles.

BERLIN

(From our own Correspondent.)

Compulsory Insurance for the Medical Profession

The amended law on medical chambers contains the provision that a chamber may establish an insurance institute, membership being compulsory for every medical man or woman residing in its district The money may be collected by contributions from the profession The Berlin Medical Chamber, which includes Berlin the Province of Brandenburg, and those parts of Posen and Western Prussia which are still under German rule, lately suggested the establishment of an institute for life assurance, the contributions were to be 60 per cent of the State income-tax and the insurance allowance was M 1200 (£60) per annum in case of invalidity or after the age of 70, and M 600 for widows and M 480 for every orphan. This scheme caused much discussion in medical circles, it was argued that the tax raised by the Berlin chamber was already rather high, and the proposed contribution would considerably increase it, whilst the benefits were much smaller than those which could be got from private insurance companies In view of growing opposition the Chamber, although authorised to take action as it wished, resolved that the medical profession in the district should vote on the proposal The result was that compulsory insurance was rejected with an overwhelming majority Of 5100 voters only 800 were in favour of it, 2500 were opposed, and 1800 abstained from voting The Democratic Party of the Reichstag has moved that State insurance shall be instituted for the legal, medical, and pharmaceutical professions and for artists and literary men It is pointed out that the great majority of people in these professions have lost their savings by inflation of the currency and that they and their families may become a burden to the ratepayers if unable to work Compulsory State insurance of the medical profession exists already in Bavaria where it is said to work satisfactorily

Pre-matrimonial Advice

A report has recently been issued by Dr Raecke on the work done by the Matrimonial Advisory Office of Frankfort-on-Main Engaged persons applying to the office were examined concerning the health of their families and on their own bodily and psychic condition, especially for the presence of venereal disease or sexual anomalies As regards heredity, it was difficult to get positive answers, 36 per cent of the individuals examined were unable to give any answer at all, and the great majority of the others could only give incomplete replies concerning the health of their relations and forbears It also proved very difficult to ascertain the psychical condition of the people who came to the office, epilepsy, for instance, could not be detected in the consulting room Sexual anomalies and venereal diseases were often concealed, whilst many of the candidates declared that they had only come at the request of their parents and asked for a certificate which could not of course be given to them without investigation being made The work of the office has not led to the results anticipated by some medical men and by the public (The Lancet, 1926 i, 881) It has had, however, a limited usefulness in that it appeals to the conscience of marriage candidates and sometimes appeases the anxiety of hypochondriacs

Early Days of Vaccination in Germany

It is now 125 years since the foundation of the State Institute for Vaccination, as has lately been pointed out by Prof H Gins in a paper read before the Berlin Society for the History of Medicine The first vaccination in Germany was performed as early as 1799 in Hanover Berlin followed in 1800 when Dr Heim, who was the leading practitioner in the city at that time used vaccine received from London The good results which he got were recognised by the Royal Department for Public Health, and a public institute for vaccination was established in 1802 in connexion with the public orphan asylum, where it was arranged that two children with cow-pox should always be at the disposal of medical men At that time vaccination was not, of course, compulsory, and pamphlets were distributed to the public on behalf of the institute in order to make it popular In course of time calf lymph was introduced and soon the institute was able to collect up to 10,000 doses of vaccine from a single animal

An Exhibition on Quackery.

In connexion with a meeting of the German Society for Combating Quackery an interesting exhibition has been held to show the methods of quacks, their advertisements, and their organisation The methods of scientific medicine, the length and intensity of medical study were compared in statistical tables with the six weeks' training advertised in certain papers for intending quacks The State library contributed to the history of quackery by exhibiting old documents in which the cities, universities, and rulers of Germany had warned the public against quacks, and had issued regulations designed to render them innocuous.

SCOTLAND

(From our own Correspondent)

The Aberdeen Joint Hospitals Scheme

In a previous letter (The Lancet, 1926, ii, 873) I described the arrangement by which the municipality was to take over the Poor-law hospitals of Aberdeen This plan has been delayed and Prof. Matthew Hay's original Joint Hospitals Scheme has now emerged upon a new plane One of the difficulties of this scheme was the disposal of the old buildings of the Royal Infirmary, but the Lord Provost of the City has now launched a public appeal for £400,000 to enable the infirmary to surmount this difficulty as to the old buildings, to secure that adequate new ones can be built, and to increase the endowed income in correspondence with the enlarged accommodation It is announced that about £200,000 has been promised already, but as the cost of the Royal Infirmary part of the scheme is estimated at £300,000 there is still £100 000 to be found, besides what is needed to maintain the proportion of endowment income to ordinary revenue

When the Joint Hospitals Scheme was originally announced, opinion was very much divided, but, just as in the case of the extension of the Marischal College over 30 years ago, Prof Hay was satisfied that ultimately the whole community would be be won over to it And now it seems that the Hospital Scheme has really become practical politics It includes, it will be remembered, not merely the new Royal Infirmary, but also the new Sick Children's Hospital (already nearly complete), the new Maternity Hospital (funds already almost adequate), the Tuberculosis Sanatorium (provided by the city), and pathological and teaching accommodation (provided by the University)

Whatever be the forces that have ended in the launching of this appeal, the supporters of the voluntary principle may congratulate themselves on the fine response for the Infirmary section But, of course, the total scheme includes the Municipal Sanatorium, the Municipal Maternity Home, the Municipal Hospital partially maintained by the municipality, and possibly one or two other elements subsidised from rates or grants There remain also the other three large medical problems the institutional treatment of infectious diseases, including the pneumonias and others until recently treated in non-municipal institutions, the institutional treatment of the sick poor, who must *all* be treated according to their needs and numbers, and the institutional preventive treatment of young children from infancy to the end of the school age These problems all have points of contact with the Joint Hospitals Scheme, and it will be interesting to watch their final adjustment As has been frequently pointed out, the municipality and the parish council have no power to select their patients or to adjust their numbers to accidental conveniences of any kind They must provide for all patients in need of treatment This fact marks the limits of the so-called voluntary principle It also demonstrates that however great the voluntary contribution to hospital service may be, it is never in any danger of outrunning the necessities There is always more than enough work both for the voluntary hospitals and for those supported out of the rates

MEDICINE AND THE LAW.

Alleged Negligence in Certification under the Lunacy Act Abortive Action

A WEEK after the Hume-Spry action had come to an end, yet another claim was heard in the High Court, in which a plaintiff alleged negligence on the part of a medical practitioner who had certified insanity The claim was that of Mrs de Freville, of Wokingham, Berkshire, against Dr A V Dill, of Brimscombe, Stroud, Gloucestershire She alleged that on June 9th, 1926, when she went to Oakridge Vicarage, Stroud, to join her husband at the home of her father-in-law, her husband ejected her forcibly from the house, and that, when she obtained entrance through the servants' door, her husband and her father-in-law kept her in the servants' hall till Dr Dill arrived She was taken to the Gloucestershire County Mental Hospital late at night, but next morning she was examined by two other doctors and declared to be of sound mind Her claim was for damages for Dr Dill's negligence in thus certifying her, she also claimed damages for assault and for false imprisonment Dr Dill relied upon the defence embodied in the Lunacy Act—namely, that he signed the certificate in good faith and that he used reasonable care. he maintained that his conclusions regarding the plaintiff's condition at the time of her certification were correct

The case came to an abrupt end in an unusual way Nearly three days were occupied by the opening speech of counsel, the evidence of the plaintiff herself, and that of various witnesses called on her behalf These included the matron and a nurse from the hospital, Dr John Marnan, medical superintendent of the hospital, Dr Thomas Cyril Smith, senior medical officer at the Second County Mental Hospital, Barnwood, Gloucester, Dr T B Hyslop, and Dr James Risien Russell On the fourth day the case for the defendant was opened, and Dr Dill went into the witness-box While he was still under cross-examination, the jury asked if they could stop the case Mr Justice Avory invited them to write their opinion upon a piece of paper If they were satisfied that the plaintiff had failed to establish her claim, they were, of course entitled, at any time after the plaintiff's case had been fully set before them, to find for the defendant as was done in the Hume-Spry case But they were not entitled to find against the defendant without giving a full hearing to what he and his witnesses had to say When his Lordship and counsel had perused the contents of the paper on which the jury's opinion was recorded, it became apparent that the jury's intervention did not take the form of a decision in Dr Dill's favour Three courses were then possible The jury having arrived at a premature conclusion adverse to Dr Dill without having heard both sides, Dr Dill could accept that conclusion and consent to judgment against himself—a step which no defendant was likely to take The second course was that the case should proceed, the judge impressing upon the jury that they must keep an open mind until they had heard all the evidence The third possible course was the discharge of a jury which had shown itself so ill-fitted for its judicial duties The judge adopted the third course If, therefore, the plaintiff persists in her action, she must begin it all over again before a fresh jury The case being thus still sub judice, comment upon the value of the evidence would be improper It may be mentioned, however, that Dr Dill, in his evidence as reported in the *Times*, complained of the small space provided in the form of the certificate for the statement of the practitioner's grounds for signing it He said he tried to condense an immense amount of detail as much as possible, and he agreed that he put down one matter under one heading in the certificate when it should have been entered under another Later, in cross-examination, he agreed that he had included under "Facts observed by myself" a statement that it was obvious that Mrs de Freville's child "cries and does not want to see her," although he had not in fact seen the child, and the entry should have been made under "Facts communicated by others" An error of this kind, of course, is not in itself negligence which entitles a plaintiff to recover damages, but it is worth mentioning here in order to impress upon practitioners who have occasion to sign certificates of this nature that any slip of this kind is fastened upon in cross-examination if the case leads to litigation Probably it does not occur to every doctor who certifies a patient that, if there is no room on the form for what he wants to write, he can set out his full entries on a sheet to be annexed to the certificate

Defence of Epilepsy on Murder Charge Fresh Hearing on Appeal

The Court of Criminal Appeal has power to hear any additional evidence on appeal and also to refer any point involving scientific investigation (which the court thinks cannot be conveniently conducted before the court) to a special commissioner for report or, if occasion arises, to appoint an assessor to the court who has special expert knowledge Where there is an issue of insanity, it seems, the Court of Criminal Appeal abrogates its functions and transfers the matter from the judicial to the executive authorities Giving judgment lately on the appeal of William Knighton, a collier, convicted at the Derbyshire assizes of having murdered his mother, Mr Justice Avory began by declaring that the Court of Criminal Appeal had frequently laid it down that, where the issue of insanity had been before a jury and evidence had been called in support of the defence, the court would not enter further into the evidence on that subject, but would leave the matter to the Home Secretary, who could more conveniently and more effectively investigate any further evidence The defence in Knighton's case was that of insanity arising from epilepsy, it was urged that the act had been committed in a state of automatism following an epileptic attack, the accused was on the best of terms with his mother, and there was no motive for the crime, he voluntarily surrendered himself to the police, and thus provided the only conclusive evidence connecting him with the crime On appeal his counsel applied for leave to call further medical evidence which was not available at the trial The application was rejected for the reason already given, and the appeal was dismissed,

The decision has had an unusual sequel It is now announced that the defending solicitors have submitted fresh evidence to the Home Secretary, and that the latter has thereupon cancelled the execution and referred the case back (as he has statutory power to do) for re-hearing by the Court of Criminal Appeal as soon as sufficient time has been given to the preparation of the case It will be interesting to see whether the fresh evidence is purely that of medical experts or otherwise There will be an opportunity to observe whether the Home Secretary can induce the Court of Criminal Appeal to abandon the rule of excluding fresh medical evidence on appeal, or whether the Court still discriminates against the medical expert.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

WASHINGTON HOURS CONVENTION

ON Thursday, March 31st, on the motion that the House do go into Committee of Supply on the Civil Service Estimates, and Estimates for Revenue Departments,

Mr R J DAVIES raised the question of the ratification of the Washington Forty-eight Hours Convention. He said that he thought they were entitled to know what had been done in respect to a decision by the Government on this very important matter The situation on the Continent of Europe was becoming very serious They were being pressed by labour organisations in other countries, and particularly by Belgium where this Convention has been ratified In relation to questions affecting labour and working people generally and the employment of women and children, the present Government, through the Minister of Labour and his Parliamentary Secretary, appeared to take no notice whatever of the Governing Body and conferences of the International Labour Organisation The only measurement of the enforcement of labour legislation in any country was the number of inspectors appointed, the number of inspections of factories and workshops made, and the number of convictions for contravention of the law The convictions in Belgium in 1925 were 650 In Czecho-Slovakia there were 1054, and in France, which they were told was more lax than any other country, the number was 6596 In Germany there were 615 convictions In Great Britain, where the enforcement of these laws was supposed to be more stringent than anywhere else, the figure as against 6596 in France was just over 1000 That was to say, that for a smaller number of working people and a smaller number of factories and workshops, for every six convictions in France there was only one in our own country The point that we should not ratify the Convention because other countries did not carry out their legislation in the same way as we did, fell to the ground in face of these figures It was understood that Belgium had ratified the Convention unconditionally, France and Germany would ratify conditionally. He also wished to bring before the House the failure of the Government to ratify the Convention relating to the prohibition of the use of white lead in paint He wished to pay tribute to the courage of the Chief Medical Inspector of Factories who, when he found that the Government had decided in favour of regulation instead of prohibition, resigned his position in the Home Office A most sinister fact was that the Federation of British Industries in its official journal stated that they had communicated with the India Office, asking that Department to send to the Bombay Government a communication to the effect that as the British Government had decided not to prohibit the use of white lead in paint, but to regulate it, the Federation asked the Bombay Government to follow the lead of the British Government, and to destroy the provisions for prohibition that it had already set up That was an appalling state of affairs The fact that there were over 200 operative painters always suffering from lead poisoning ought to induce any Government of any political colour to ratify this Convention

Mr BETTERTON Parliamentary Secretary to the Ministry of Labour) said that ratification was not to be obtained merely by registering ratification at Geneva, or by passing a resolution of the House It involved the introduction of a Bill to bring the legislation of this country into conformity with the Washington Convention, and such a Bill naturally required very careful consideration If it was right to ratify, the Government must at least know what the cost would be The whole matter was now under the consideration of a Cabinet Committee

Captain KING (Financial Secretary to the War Office) replying for the Home Office on the question of the White Lead Convention, said it was quite clear that there was no obligation on this Government or on any other to ratify that draft Convention So far as the question of Bombay was concerned, he was not competent to answer for the India Office or for the Bombay Government The Home Secretary had announced that the Regulations were on trial It was hoped that they would be able to remove the danger from the use of lead paint But if that was not so, the Government would come to the House for further powers

The question that the Speaker do leave the chair was agreed to by 213 votes to 77

SANDSTONE WORKERS AND PHTHISIS

The House then went into Committee of Supply, Captain Fitzroy in the Chair

On a vote of £57,110 for expenditure in respect of the Houses of Parliament Buildings,

Mr GARDNER moved to reduce the vote by £100 He said that it was amazing that in the Memorandum which had been prepared in respect to this expenditure, the question of the health of the operatives who were to be called upon to work the Stancliffe stone which it was proposed to use for the repair of the Houses of Parliament, had never been mentioned. It could not be beyond the knowledge of His Majesty's advisers that danger existed in connexion with the working of this stone, because the Office of Works, when it had work to be done with that kind of material, paid the men an extra sum per hour because of the danger of working it Sir Thomas Legge, who was till lately the Senior Medical Inspector of Factories, and who throughout his Civil Service career was engaged in reporting to the Government on work of this kind said —

> "In Great Britain the quarrying and dressing of sandstone, whether in Derbyshire, Yorkshire, or round Edinburgh—Edinburgh is largely built of freestone—must have cost a holocaust of lives The geology of Derbyshire, indeed, has been marked out simply by the death rate from phthisis—high on the sandstone areas, low on the limestone This point is convincingly summarised by the Registrar General's figures, showing that, as compared with 142 of the average male population between 25 and 65 years of age who die of phthisis, there die 127 granite dressers, 129 limestone dressers, and 415 sandstone masons"

Those figures were appalling enough, and for the Government to embark upon this scheme without first taking them into consideration was negligent to say the least of it Sir Thomas Legge went on to say

> "The ultimate effects of silicosis are even slower to show themselves than in the case of lead poisoning Years invariably elapse before the shortness of breath—the result of the slow but sure encroachment on the air spaces—which is the cardinal symptom, makes work difficult, and, to add to the trouble, the tubercle bacillus is as likely as not to find a nidus in the weakened lung At present, unfortunately, methods of removing the dust at the point of production in chipping and dressing by hand have failed, although invention may yet find a way Wetting the stone is a very partial success"

It was often suggested that the masons had only to wet the stone and their death-rate would be lowered, but those who knew the work knew that the man who wetted the stone hindered his output, and for economic reasons therefore he had to take the risk of disease The Medical Officer of the Derbyshire County Council had conducted an inquiry into this subject Taking the death-rate per thousand from 1901 to 1910, the rate among 124 persons, gritstone workers, was 13 7 from phthisis Out of 126 stone workers, some in limestone in the two Matlocks and the two Darleys, the death rate was 7 per 1000 Taking the gritstone and limestone workers generally, the rate was 5 per 1000 Among the persons employed in and about limestone quarries and works, the rate was 1 71 per 1000 Among limestone workers themselves it was 1 52 per 1000 Among persons employed in and about coal-mines in the same district the rate was 68 per 1000 The standard phthisis death-rate was 77 per 1000 Therefore, the workers on this kind of sandstone had to take the greater risk of a death-rate of 13 7 per 1000, as against the average phthisis death-rate of 77 If they compared figures compiled for the same years in respect of the workers in Portland stone, they found that the death-rate among the masons was 1·4 per 1000, among the labourers 1 0, and for all other trades 1 1 per 1000 Dr Brown, one of the medical officers connected with the Home Office, gave a report to that Department in 1922 in which he said that the development of this disease was remarkable It grew in slow stages, and the men who suffered from it, although they appeared to be the same, ultimately died very quickly from its effects If this kind of stone was introduced into London, Mr Gardner continued, they would raise the maximum amount of disease among the men who had to work it, or alternatively they would have to bring men from the area from which the stone came and they would have to send them back to their own districts and compensate them It might be suggested that special tools, such as the pneumatic tool could be used, but the operatives in London were opposed to the use of this tool, and rightly so, because it only expedited the work and aggravated the disease Portland stone was proving its durability, and was being used in place of sandstone, even in the sandstone areas

Captain KING, replying on behalf of the Government, said that in 1922 the sandstone quarry owners in Derby decided to have an examination of their employees They instructed the local medical officers of health to examine 291 operatives Out of this number 5 were found to be suffering from silicosis and 7 from lung diseases Eighty-four of the men were between 40 and 49 years of age, 51 were between 50 and 59, and 21 were 60 years of age and over This showed that the working of this sandstone was not very injurious All the medical officers of health reported favourably on the condition of the men examined The medical officer of health of the North Darley Urban District Council supplied a statement of the death-rate from phthisis in his area from 1909 to 1920 The figures for 1919 and 1920 were representative of the remainder In 1919 the death-rate per 1000 from phthisis was 0 34, the number of deaths from that disease was one a female In the same year the rate for England and Wales was 1 55

Mr **Gardner** You cannot make comparisons of that kind, you must take it in connexion with the men engaged in that particular area

Captain **King** said that it was necessary to consider the state of health in the whole of that area He did not consider that there existed any really satisfactory statistics to prove what was being contended either one way or the other There was no doubt that those who worked sandstone did suffer to a certain extent from silicosis, and that complaint was not unknown among those who worked limestone The matter however, had been carefully considered, and they intended to take every possible precaution to secure the health of those who worked on this stone, not only by damping the stone, but in other ways The workshops in which the men would work within the precincts of the Palace of Westminster would have roofs which could be removed and opened completely in fine weather, so that the men would be working practically in the open air By these precautions he hoped that no bad effects on the health of the workmen would be experienced Hitherto the Home Office had never been requested to prohibit the use of silicious material and it was unreasonable to suggest that while all other buildings and organisations in this country were still allowed to use this particular type of sandstone the Government should be denied the use of it in this case where it was considered to be the most serviceable stone for the purpose

The motion to reduce the vote was negatived without a division

Nursing Homes (Registration) Bill.

On Friday, April 1st, Mrs **Philipson**, in moving the second reading of the Nursing Homes (Registration) Bill, said the principle of the measure had already been approved by a Select Committee of the House That Committee came to the conclusion that the existence of a genuine need for the registration and supervision of nursing homes was fully established In the first place the premises of many nursing homes were structurally defective and unsuitable, secondly the Committee were deeply impressed with the urgent need for registration and supervision, particularly in regard to the class of home which catered for poor people and senile chronic cases In the third place they considered that in many nursing homes the accommodation for the nursing staff was seriously defective Certain progressive areas such as London and Manchester had already in operation local Acts providing for the registration of maternity homes, and in 1926 Parliament passed a general Act providing inter alia for the registration of maternity nurses The Select Committee came definitely to the conclusion that the registration and supervision of maternity homes should be made part of one comprehensive scheme covering all nursing homes Following the principle adopted in the Midwives and Maternity Homes Act 1926, the Select Committee recommended that the authorities to administer any system of registration should be the county councils and county borough councils under the general supervision of the Ministry of Health The Bill substantially gave effect to these recommendations It proposed that the local authority should have power to refuse registration on the ground that the applicant was not a fit person, or that the premises were unsuitable Many homes were managed by persons who were not qualified nurses, and it was thought that it would be arbitrary and unfair for Parliament to deprive these people of their livelihood The Bill did not propose in the case of nursing homes in existence at the commencement of the Act to refuse registration if the person in charge was unqualified, but it did propose to insist that the person who was superintending the actual nursing of the patients should be a qualified nurse While maternity homes were brought into the scheme by the repeal of Part II of the Midwives and Maternity Homes Act, 1926, a special provision was inserted because provision had to be made for the special qualification of certified midwives who normally would be found in many of these establishments In the event of a local authority refusing to register, or cancelling registration, there would be power to appeal to a Court of Summary Jurisdiction, and if the need arose, to Quarter Sessions The duty of inspection was to be carried out by officers of the local authority, and there was a proviso designed to secure that there should not be any inquiry into the medical records of individual patients, which was a confidential matter Under Clause 6 there was provision for the temporary exemption of certain establishments of a charitable nature, and an appeal was allowed if any person was aggrieved by the refusal of a local authority to grant exemption Clause 9 gave a definition of "nursing home" which was designed to exclude certain establishments which were maintained by public authorities or were constituted by special Act of Parliament or incorporated by Royal Charter The definition also excluded any institution which was liable to inspection under the Lunacy Act or the Mental Deficiency Act The definition of "qualified nurse" in Clause 9 brought it into relation with the Nurses' Registration Act, 1919 Clause 10 provided for proper safeguards for the repeal of local legislation as it was very desirable that this general Act should supersede local Acts in various parts of the country If Parliament passed this Bill it would be a safeguard against abuses without unduly interfering with well-conducted establishments and without impairing the privacy of treatment that patients and their medical advisers desired The Bill fulfilled its purpose through existing machinery, and aimed at raising the standard of the conditions under which the sick were nursed, and also the conditions under which the nursing profession performed their duties

Mr **Gerald Hurst**, in seconding the motion for the second reading, said the movement for reform in this matter originated among the nurses themselves The Norwich Nursing Association first raised this question some years ago, because they were appalled by the fact—which was still a fact to-day—that there were up and down the country some hundreds of institutions which called themselves nursing homes, although there were not any qualified nurses on the staff, and although it was an absolute mockery to call such institutions homes As the law stood at present, the words "nursing homes" connoted nothing, and had no legal significance. The result was that the public were persuaded again and again to enter institutions which were, in substance, bogus nursing homes Those who went to a nursing home ought to know that it was not a bogus one and at present, even in the case of homes which were owned by medical men, those doctors might be quite ignorant of the qualifications and characters of the nurses and the accommodation and amenities of the home which they controlled and ran Inspection need not necessarily be inquisitorial A reasonable inspection by qualified persons at reasonable times would, he was sure be objected to by no one who carried on a properly-conducted nursing home There was in the Bill, as now drafted, a mistaken view put forward as to the person who should carry out the inspection The Committee recommended that it should be carried out by the medical officer of health, assisted by his technical staff that was to say, a nurse qualified to go into the matters of nursing, or a sanitary officer to go into questions of sanitation as the case might be In the Bill the word "inspector" was used That was not what the Committee wanted He thought that the practical unanimity among expert opinion and non-professional opinion on this question was eloquent as to the need for this Bill The reason why the Bill only dealt with future maternity homes was that existing nursing homes were effectually and completely covered by the Act passed last year With regard to future homes, the condition to be met before registration was granted, was that the home must be under the charge either of a doctor or a qualified nurse, and then the Bill ought to read, in his view "in that case there should be a proper proportion of qualified nurses on the staff" According to the evidence submitted to the Committee it cost no more to employ a qualified nurse than an unqualified one The evidence given before the Committee satisfied all the members, including the medical members, that abuses were rife in homes owned by doctors, as well as in those run by unprofessional persons He was not reflecting on the whole body of the medical profession, but the fact was established that homes owned by doctors were not necessarily immune from the abuses to which other nursing homes were liable No doctor of any status would object to having his home registered Registration conferred a status rather than a stigma. With a view to meeting hard cases, as far as existing institutions were concerned, the definition of a qualified nurse had been enlarged so as to include, not merely State registered nurses but those who, before the commencement of this Act, had completed a three-years course defined in the Bill

Replying to Mr **A. V Alexander**, Mr **Hurst** gave it as his opinion that if in a convalescent home nursing was given, it would certainly come within the definition of a nursing home

Sir **Douglas Newton** moved the rejection of the Bill, which he said provided for undue and unnecessary centralisation The authorities who would be responsible for administering the Bill would be the council of every county and county borough That cut out the whole of the non-county boroughs of the country These non-county boroughs which were the local education authorities and the authorities under the Maternity and Child Welfare Act, ought to be empowered to administer this Bill If the powers of the Bill were vested in the county council and they had no power to delegate their functions to other local authorities, they would be put to considerable additional expense by increase of staff and travelling expenses of officials to and from the nursing homes He was fully in sympathy with the Bill in regard to the care and welfare of the sick

Mr **Harrison** seconded the rejection of the Bill

Dr **Drummond Shiels** said he hoped the Bill would have a smooth passage through the House He did not think that the general public or the ordinary members of the House realised the need for this legislation. The members of the Select Committee—he spoke for himself at any rate—had no idea that the matter was so serious, and that a Bill of this kind was so much required. It was not a matter entirely of the status of the home; they found that some homes where very large fees were charged, were unsatisfactory, but what they were most impressed with was the number of cases of chronic senile poor people who were kept under deplorable conditions. In one case a home was run by a man and his wife and one small maid-of-all-work, who did the nursing and the housework as well, and attended to 15 or 20 people, practically all of whom were bed-ridden, and could not attend to themselves. The house was filthy, the bed linen was not changed for weeks, the patients and their surroundings were verminous, and the matron or her husband, either separately or together, were frequently under the influence of drink. Regulations should be brought about to prevent such homes from existing at all. The great problem of course in this, as in many other matters, was poverty. These people were paying from 15*s* to 25*s* per week. It was quite impossible to get even adequate food and housing for that sum apart altogether from nursing. Such people, if that was all they could pay, ought to be in a public institution. He believed that in that connexion the increasing use of Poor Law hospitals, with the removal of the stigma would be a very great help to the solution of this problem. He was glad that an attempt was made in this Bill to see that nurses were properly housed. They had very bad evidence before the Committee, even in regard to good homes, on that point. He hoped also that there would be a quota of fully trained nurses in each home. Only slight alterations were necessary to make the Bill perfectly suitable to Scotland, and he would like it to be applied to that country.

Sir RICHARD LUCE said, that as a member of the Select Committee he supported the second reading of the Bill. He came to the question with an open mind when the Committee began their investigation. In days gone by he had found homes in which he had to work which were not as satisfactory as he would have liked, but he had not in recent years at any rate, come to the conclusion that there were any very great scandals going on in such nursing homes as were brought to his notice. But when the Committee started to take evidence his views very rapidly changed, and he soon came to the conclusion that there was a very real need for the registration of these homes. The trouble was mostly not in the regular surgical nursing homes, but more in those which were the sort of odd places that took in a poor class of patients for small fees, and also certain other places which did not hesitate to take a class of patient which they were totally unfitted to deal with. When the original Bill was mooted some two years ago, there was a good deal of objection from the medical profession on certain grounds. He thought they had not realised the real seriousness of the question. Though there was no general objection to registration, the body of the medical profession did lay down certain rules which they would consider necessary. They were very anxious that there should be a delegating body which would be responsible for granting registration, and that there should be representation of medical men and also of nurses. Another great point that was made was that there should be sanctity of professional secrecy between patient and doctor, which he thought had been fairly met in Clause 5. Then there was at first a great demand on the part of the medical profession that homes under the charge of medical practitioners might be exempted, if not from registration, at least from inspection. That exemption was permitted in the Midwives and Maternity Homes Act last year. He thought that the evidence given before the Select Committee, which proved conclusively that certain homes owned by doctors were not above suspicion, had considerably modified the original view of the medical profession, and they would no longer demand the inclusion of an exemption clause. Personally he thought it would be a great mistake to insert such a clause. He saw no objection from the medical point of view to the Bill as it now stood. If the measure was carried out in the proper spirit, there would be four great things gained. They would have gained a coördination of the two kinds of homes which were, previously separated. There was no great difference between a maternity home and a nursing home. By bringing the two classes under registration, they would bring about a coördination which was necessary and reasonable. Further, if the Bill became law, they would secure that nursing homes would have suitable buildings and be properly equipped for the nursing profession according to the class of case they took in. There would also be guaranteed a reasonable standard of nursing. It was quite impossible for every patient to be treated entirely by completely qualified nurses; there were not enough in the country to provide for that purpose, and there must always be a certain number of people who were under training, or passing up to the stage of training. In general hospitals there was only a small proportion of qualified nurses, and there was always a large number of pupil nurses who were undergoing training who did a great deal of the work of nursing the sick in hospital, and there was no reason why a similar sort of arrangement should not be allowed in nursing homes as long as the requisite standard of nursing was maintained. There would also be considerable gain in the case of the nurses themselves. The Committee received a considerable amount of evidence from the proprietors of nursing homes, and from others as well as doctors, that it was essential that the supervising authority should be entirely independent. The Committee felt that it was not wise in the ordinary way that the supervising authority should be a small one. At any rate, it ought to be a borough of very considerable size with a whole-time medical officer of health and complete staff. There were one or two points of criticism, really Committee points, which struck him in reference to the Bill. Clause 1, sub-section (3) (c) did not, so far as he could make out, allow of the patients in maternity cases being attended by a doctor. There might also be difficulties about a nursing home certifying the cause of the death of a patient. It was no business of a nursing home even to have any knowledge of the cause of death under certain circumstances. One could realise that it might be necessary in maternity homes where a considerable number of septic cases were occurring, and when it was known that septicæmia was prevalent in the home; but that was a question of notification rather than of letting them know the cause of death. In the Bill passed last year dealing with the registration of births and deaths, it was laid down that it was the duty of the doctor to send the certificate as a confidential document to the registrar. Therefore, it was not within the rights of a nursing home to have any knowledge of the cause of the death of a patient who had died in the home. It might be a matter of very considerable importance in many cases that the cause of death should not get out, even to the nursing staff. A patient might be suffering from some disease which was due to alcohol. It was not right that that cause of death should be given out to everybody far and wide. He thought there was also some little doubt about the question of the qualified nurse which might be cleared up in Committee.

Major ELLIOT (Under Secretary of State for Scotland), who apologised for the unavoidable absence of the Minister of Health, said that the view of the Government was that, taking the measure as a whole, it was quite reasonable that the House should give it a second reading and place it on the Statute Book. He thought that Sir D Newton and Mr Harrison had made out a strong case in favour of the non-county boroughs. That matter might be further considered in Committee. The number of homes concerned was perhaps larger than the House realised. The Registrar-General in his returns mentioned that there were over 2000 convalescent and nursing homes in England and Wales and, in fact, the number might run as high as 3000. It was quite possible that, with such a large number of institutions, abuses might have crept in. If this Bill was passed they would be able to see whether the beneficial results which had been found in places like London and Manchester would be paralleled in the case of the nursing homes in other places throughout the country.

Dr VERNON DAVIES said that the point which the House must consider was that the matter with which the Bill sought to deal was nothing less than a scandal and must be dealt with as quickly as possible. It was a great step in advance that the medical profession had withdrawn their objections to the inspection of homes owned by doctors. What they were aiming for was that the health of the country should be looked after by competent and trained people, medical men and nurses; that all abuses should be done away with, and that nothing should be hidden.

The motion for rejection was not pressed, and the Bill was read a second time and committed to a Standing Committee.

MIDWIVES AND MATERNITY HOMES (SCOTLAND) BILL.

The Midwives and Maternity Homes (Scotland) Bill has been considered by the Standing Committee on Scottish Bills. Sir CYRIL COBB was in the chair.

On Clause 1 (which amends the Midwives (Scotland) Act of 1915) Mr MAXTON moved an amendment to confine the liability to prosecution and penalty to unqualified persons who attended women in childbirth "habitually and for gain." He said that while it was very desirable that the object of the Bill should be achieved, and that highly-trained women should look after the responsible work of midwifery, it was also desirable that the ordinary decencies of neighbourly life should not be made impossible by the operation of this clause, which was so severe that the onus was put on a woman who rendered assistance in these cases to prove that she had only done so in a case of sudden and urgent necessity. He held that the responsibility should be on the authorities to prove that such a woman had been in the habit of doing this work for payment.

Mr **BARCLAY HARVEY**, who was in charge of the Bill, resisted the amendment While there was no desire to prosecute any woman who came in to help in a case of emergency, the amendment, he said, would knock the bottom out of the clause

Dr **DRUMMOND SHIELS** said that in Scotland maternal mortality had remained high for practically two generations, and there had been very little diminution The neighbourly attentions to which reference had been made were responsible for a great deal of that maternal mortality The main cause of death in these cases was puerperal sepsis, which was due to the neglect of aseptic precautions which unqualified persons could not be expected to understand He suggested that Mr Maxton's point would be met by an amendment which he (Dr Shiels) intended to move later

Mr. **MAXTON** indicated that he wished to press his amendment

Dr **VERNON DAVIES** said that the insertion of the words "habitually and for gain" provided a very bad loophole He thought that the object of Mr Maxton was covered by the clause as it stood

Lieut Colonel **FREMANTLE** asked the Committee not to accept the amendment which, he said, would condemn many mothers to the risk of putting their lives in the hands of incompetent women

After further discussion,

Major **ELLIOT** (Under Secretary for Scotland) said that the position of a woman about to give birth to a child had always been regarded as something exceptional both by Scottish law and the law of other countries It was the only case in which there was a statutory prohibition against action by unregistered persons There was no prohibition against engaging in medical practice but there was a prohibition against engaging in midwifery practice This amendment would make an exception to the law Dr Shiels had an amendment on the paper which he thought constituted a reasonable compromise, although he was advised that that amendment would require the addition of certain words to cover also the case of the registered medical practitioner When the time came for Dr Shiels' amendment he would advise those in charge of the Bill to accept it In the meantime he suggested that the Committee should negative Mr Maxton's amendment

Mr Maxton's amendment was rejected by 26 votes to 12

Dr **SHIELS** moved an amendment providing that there should be no prosecution in a case where reasonable efforts had been made to obtain the services of a duly qualified medical practitioner, or a person certified under this Act

The amendment was agreed to.

Mr **MAXTON** objected to a proviso which exempted medical students from the provisions relating to unqualified attendance

Major **ELLIOT** assured the hon member that the General Medical Council was duly cognisant of its responsibility in these cases In all cases where students were sent out to midwifery cases they had had previous experience in hospital, and they went out to their earlier cases with a registered medical practitioner from the school which they had been attending

On Clause 8 (Registration), Dr **SHEILS** moved an amendment to provide that improper sanitation should be one of the grounds on which an application to register a maternity home might be refused

The amendment was agreed to

Major **ELLIOT** moved an amendment providing that in the case of a maternity home which was not in existence at the commencement of the Act, the person having the superintendence of the nursing of the patients should either be a qualified nurse or a certified midwife He explained that this amendment strengthened the provisions of the Bill and made it clear that a person having the superintendence of the nursing must have the C M B qualification

The amendment was agreed to

On Clause 12 (Inspection of Maternity Homes), Mr **BARCLAY HARVEY** moved an amendment providing that nothing in the Act should be deemed to authorise any officer sent to inspect a maternity home, who was not a duly qualified medical practitioner, to inspect any medical record relating to any patient in such a home He said that he understood that this covered a point which had been made by Dr **VERNON DAVIES** It should provide a sufficient guarantee of secrecy

The amendment was agreed to

On Clause 14 (Power to Exempt Certain Institutions from Registration and Inspection),

Dr **VERNON DAVIES** moved an amendment to secure that the local supervising authority might exempt any hospital or similar institution not carried on for profit and not used mainly as a maternity home He said that the reason for this amendment was that there were certain homes for women where girls were taken in and occasionally gave birth to a child

Dr **SHIELS** said that although he supported the amendment he was rather unhappy about the terms of it He quite recognised that in a public voluntary hospital inspection might not be necessary, but there were many institutions, especially of a charitable or semi-charitable nature, which were conducted on very unsatisfactory lines, and he hoped that the Scottish Board of Health would exercise a little supervision

Lieut -Colonel **FREMANTLE** said that he understood the object of Dr **DAVIES**, but he thought he was proposing a phrase which it would be impossible to administer

Major **ELLIOT** said that his hon friends could thresh the matter out for themselves As the hon member in charge of the Bill did not raise any objection to the amendment he did not think that it was a matter in which the Government, as such, should intervene The amendment might, he thought, be accepted

The amendment was agreed to

On Clause 15 (Interpretation), Major **ELLIOT** moved words to make it clear that "qualified nurse" meant a person registered in the general part of the Register required to be kept under the Nurses' Registration (Scotland) Act 1919, or a person who had before the commencement of this Act completed a three years' course of training in a hospital which, during the period of her training, or subsequently, had become a training school approved by the General Nursing Council for Scotland, the General Nursing Council for England and Wales, or the General Nursing Council for Northern Ireland for the purposes of admission to the general part of such register

The amendment was agreed to

The Committee stage was concluded and the Bill was ordered to be reported to the House

SALE OF FOOD AND DRUGS BILL

This Bill passed through Committee of the House of Lords on Tuesday, April 5th, without amendment

---

HOUSE OF COMMONS

WEDNESDAY, MARCH 30TH.

Medical Scales for Merchant Ships

Mr **CONNOLLY** asked the President of the Board of Trade how often the standard list of drugs and appliances which all sea-going ships must take with them was revised in order to keep pace with modern developments —Sir **BURTON CHADWICK** (Parliamentary Secretary to the Board of Trade) replied The last revision of the medical scales for merchant ships was issued in 1924, and the preceding one in 1912

Outbreak of Small-pox in Dundee

Mr **JOHNSTON** asked the Secretary of State for Scotland, whether he could give the House any information regarding the outbreak of small-pox in the congested area in Dundee, if the source of infection had been traced, and what precautions were being taken against the spreading of the disease Sir J **GILMOUR** replied I understand that up to this morning 42 cases of small-pox had been diagnosed in Dundee Of these, four are adults, two are persons of 16 years of age, and the remainder are children of school age or under With the exception of the four adults, who were vaccinated in infancy, all the cases were unvaccinated The disease is very mild in type, and the outbreak is confined to a limited area in the east end of the city The source of infection has not yet been traced, but a member of the staff of the Medical Officer of Health is wholly engaged in endeavouring to discover how the disease reached Dundee All cases are removed to hospital and steps are immediately taken to carry out disinfection Another pavilion is being erected with the utmost expedition at the hospital, and, in the meantime, a marquee is being used as emergency accommodation, and two others are available if required Doctors, inspectors and nurses are carrying out a house-to-house visitation in the infected area, to keep the outbreak under control, and cases of contact are removed to a reception house or kept under daily medical observation in their homes A special staff is engaged on vaccination work under the direction of the Medical Officer of Health, who is, in addition supplying lymph to general practitioners free of charge Lymph for 16 000 persons has so far been issued, centres have been established at which anyone may be vaccinated at any hour of the day, within reasonable distance of his residence, and arrangements are being made for the vaccination of the staffs of workplaces and the inmates of institutions, etc Vaccination is also being carried out at schools As a precautionary measure, steps are also being taken to make chicken-pox compulsorily notifiable throughout Scotland without delay, but meantime this is already in operation in Dundee by arrangement with medical practitioners

Mr **JOHNSTON** Do I understand the right hon gentleman to say that all these cases have arisen in the congested areas in the east end of Dundee, and if so can he take other steps than merely vaccination to limit or prevent the spread of this disease ?

SIR J GILMOUR I think my answer will show that every possible step is being taken to deal with the outbreak at the source by the method of vaccination

Mr JOHNSTON Has the right hon gentleman taken any steps of a sanitary nature to deal with the outbreak ?

SIR J GILMOUR Yes, Sir The officers responsible for the health of the city are taking every possible step in every direction

Dr. VERNON DAVIES Will the right hon gentleman try to ascertain how many so-called conscientious objectors are now submitting to vaccination ?

No answer was given

Health Year Book of the League of Nations

Mr BENJAMIN SMITH asked the Secretary of State for Foreign Affairs why no report regarding conditions in Great Britain was included in the Health Year Book recently published by the League of Nations —Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied A comprehensive survey of the health conditions of the country is contained in the annual reports of the Ministry of Health, and of the Chief Medical Officer and the Registrar-General My right hon friend is not clear that the value of a summary, necessarily much condensed, of the statistics already published would be commensurate with the labour and cost involved in its preparation, but the question will be further considered

Bakehouse Used as Sleeping Apartment

Mr WILLIAM THORNE asked the Home Secretary if his attention had been called to the remarks made by the coroner at the inquest held at Hackney on the 23rd instant in connexion with the death of a baker who had been sleeping in a bakehouse for a considerable time, and whether he intended taking any action in the matter —Sir WILLIAM JOYNSON-HICKS replied I am informed that the local authority, who are responsible for the administration of Section 100 of the Factory and Workshop Act, 1901, have decided to take proceedings against the occupier

THURSDAY, MARCH 31ST.

Pensioners and Light Metal Limbs

Major HILLS asked the Minister of Pensions if he was aware that a number of pensioners with below-knee amputation had asked to be fitted with light metal limbs in preference to wooden limbs, and that in most instances such applications had been refused, the number of cases in which pensioners with below-knee amputation had been fitted with light metal limbs, and in how many of these cases the pensioner had afterwards reverted to the use of wooden limbs —Major G C TRYON replied I have no information to confirm the statement made in the first part of this question but, on the contrary, I am informed by at least one of my largest limb-fitting centres that a number of pensioners who have been fitted with metal limbs wish to exchange them for the new and lighter willow limbs and that more complaints are received from pensioners wearing the metal limb than from those wearing the wooden type The number of cases in which pensioners with below-knee amputations have been fitted with metal limbs, was, in the 12 months ending February last, about 2000, but I have no specific record of the number of cases asked for in the last part of the question

Relieving Officers and Medical Relief

Mr ROBERT RICHARDSON asked the Home Secretary whether he was aware that by the operation of Section 62 of the Rating Act, 1925, and of the Overseers Order, 1927, the overseers would be abolished on 1st April next, and their powers and duties as to relief from poor rate in cases of sudden and urgent necessity and medical relief would be transferred to any relieving officer, that the power of any justice of the peace to order the overseers in certain cases, by writing under his hand and seal, to give temporary relief in articles of absolute necessity but not in money and, in certain cases, to give a similar order for medical relief only, would become a like power to give an order to any relieving officer, and whether he proposed to draw the attention of the justices of the peace to this change in the law —Sir W JOYNSON-HICKS replied Steps are being taken to bring the provision to the notice of justices

Committee on Sexual Offences

Miss WILKINSON asked the Home Secretary whether, in view of the fact that last Session he proposed to delay the introduction of any legislation based on the Report of the Committee on Sexual Offences until the Committee on Young Offenders had reported, he would take advantage of the fact that this latter had now reported and introduce legislation at an early date —Sir W JOYNSON-HICKS replied It will take me some time to complete my consideration of the very important recommendations of the Committee on Young Offenders which has just reported but I adhere to my intention to deal with the recommendations of the two Committees together so far as they require legislation

Certification of Boy under Lunacy Act

Major ALAN MCLEAN asked the Home Secretary whether his attention had been drawn to the case of Reggie Ford, aged 12, who was in 1922 committed to an industrial school and was now in a mental hospital, and whether he would cause inquiries to be made as to the circumstances leading to his present condition —Sir W JOYNSON-HICKS replied The case of this little boy was brought to the notice of my predecessor, who made careful inquiry, and on June 27th, 1924, stated in reply to a parliamentary question that he was "Satisfied that the magistrates, who included two women magistrates, dealt with the case with the fullest sympathy and with a desire to do what was best for the boy. The parents admitted that he was given to pilfering, that he was falling under the bad influence of older boys, and that they were unable to control him, and they asked that the boy might be sent away to school" I agree entirely with my predecessor's statement When the boy was received into the school in January, 1923, he was said to suffer from a nervous disorder, and special attention was given to him under the supervision of the school doctor As the nervous symptoms increased he was examined by a Home Office Medical Inspector, who came to the conclusion that the boy was probably suffering from the after-effects of encephalitis lethargica Arrangements were then made for the transfer of the boy to another school where, with the coöperation of the Somersetshire Education Committee, a special nurse was engaged for him for a considerable time and where he received unremitting care Arrangements were also made for his special observation in a London hospital The boy, however, steadily grew worse and, as it was impossible to keep him in the school he was discharged to the care of the Guardians in July, 1925 Since then I understand, that the boy has been certified under the Lunacy Act and is now in a mental hospital

Committee on Registration of Opticians

Mr ROBERT WILSON asked the Minister of Health whether he was now in a position to announce the names of those who would form the committee to inquire into the registration of opticians ?—Mr CHAMBERLAIN replied The Committee which has been appointed jointly by my right hon friend the Secretary of State for Scotland and myself has now been constituted as follows —Mr F B Merriman K C, M P (*Chairman*), Mr O Aves, Mr W B Barker, Mr H B Brackenbury, M R C S, Mr L G Brock, Mr E Treacher Collins, F R C S, Mrs W L Courtney, Lord Cozens-Hardy, Mr R J Davies, M P, Mr H L F Fraser, LL B, Dr C O Hawthorne, F R C P, Mr G E Houghton, Sir Henry Keith, and Mr J S Henderson, of the Ministry of Health (*Secretary*)

Physical or Medical Disability in Air Force Recruits

Mr HORE-BELISHA asked the Secretary of State for Air what percentage of new recruits for His Majesty's Air Force were discharged on account of some physical or medical disability in 1926 within 12 months of their acceptance —Sir S HOARE replied The answer is 1·46 per cent

Death-rates of Centenarians

Mr DAY asked the Minister of Health the number of persons, both male and female, whose age exceeded 100 years and whose death had been recorded in England and Wales for the five years ended to the last convenient date —Mr CHAMBERLAIN replied —The following are the figures asked for by the hon member Deaths at age 100 and over in England and Wales

Year	Males	Females	Year	Males	Females
1922	18	59	1925	23	69
1923	22	74	1926*	27	61
1924	22	64			

* The figures for 1926 are provisional

The New Food Preservative Regulations

Mr CAMPBELL asked the Minister of Health, if, in view of the new regulations affecting the use of preservatives in food, he had issued, or proposed to issue, to local authorities a suggestion that they should take special pains to warn consumers that certain foods should not be expected now to keep so long in a condition fit for human consumption —Mr CHAMBERLAIN replied No, Sir, I do not propose to make any such suggestion, since only experience can show how far, if at all, the keeping properties of food in the consumers' houses would be affected by the absence of preservatives I may say, however, that in making the regulations I had regard to the circumstances of the ordinary household, and to the fact that most of the principal foods affected were already being sold without preservative by some traders

MONDAY, APRIL 4TH

Mentally Defective Children in Surrey

Mr ROBERT MORRISON asked the President of the Board of Education how many ascertained mentally defective children there were in the elementary education area of the Surrey county council, for how many of these was appropriate provision made by the local education authority for how many was no education of any kind provided, and what steps, if any, he had taken to secure that appropriate education was given to those mentally defective children not receiving it in Surrey —Lord E PERCY replied According to returns furnished by the Surrey Authority, there were in their area in 1926, 259 ascertained educable mentally defective children, of whom 41 were at special schools, 133 at public elementary schools, and three at other institutions The question of making further provision for children of this type is, I understand, engaging the attention of the Authority

Vaccination Technique in Southport

Mr GROVES asked the Minister of Health whether he was aware that the medical officer of health for Southport received a letter from the Ministry of Health stating that the severity of the vaccination reaction reported from Southport had been noticed in other districts and appeared to be caused more by the technique used in vaccinating than by the virulence of the vaccine lymph, and suggesting that a single incision four-fifths of a centimetre long should be made and no criss-cross incision, and whether this was the official view of the Ministry —Sir KINGSLEY WOOD replied My right hon. friend is aware that a letter was written by a medical officer of the Ministry (after having made a local inspection) to the Medical Officer of Health of Southport generally on the lines set out in the first part of the question except that it was made clear that four marks should be made, *each* by a single-line incision, not 4/5 centimetre but 4/5 millimetres long The official view of the Department is set out in the instructions to vaccinators under contract, and the suggestions made in the letter are quite consistent with that view

TUESDAY, APRIL 5TH.

Silicosis among Stone-workers

Dr VERNON DAVIES asked the Secretary for Mines to give for the last three years for which statistics were available the number of cases of silicosis reported among stone workers, the number of deaths from this disease, the number of cases which developed pulmonary tuberculosis and died therefrom; and the kinds of stone which proved to be most liable to produce silicosis among stone workers Colonel LANE FOX replied Silicosis is not in general a disease which is required to be reported and the detailed information asked for is therefore not available, but it may be stated that the kinds of stone most liable to produce silicosis are the more highly silicious sandstones and granite More information will be available on this point when I have the results of a medical inquiry into the dust danger among workers in sandstone which has been undertaken by my right hon. friend the Home Secretary in which my Department is collaborating

Mr HARTSHORN. Can the right hon. gentleman say when he expects to obtain that report?

Colonel LANE FOX No Sir

Mr PALING In view of the increase in the number of cases of silicosis is there any prospect of it being scheduled as an industrial disease?

Colonel LANE FOX Clearly we must have the report before we can take any action of that kind

---

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Plans have been prepared for an extension of the buildings, and private paying wards are to be provided, together with better accommodation for the nursing staff Last year more than 1000 accident and urgent cases were attended and 2036 operations, 469 of them of a major character, were performed

ANCOATS HOSPITAL—This hospital, which is situated in one of the most crowded industrial areas of Manchester, will celebrate its centenary in August, 1928, and will shortly make a special appeal for help in carrying out improvements, including a new ward of 100 beds There is a waiting-list of 000, and it is stated that not half the patients on it will ever be admitted Even with the present accommodation 20,000 accidents and casualties are treated annually At least £100,000 will be required for the establishment of the new buildings It appears from the record of the hospital that, for the first quarter of its century of life, it spent anything up to £50 a year on leeches for blood-letting

Medical News.

UNIVERSITY OF DURHAM—At recent examinations the following candidates were successful in the undermentioned subjects —

THIRD EXAMINATION FOR THE DEGREES OF M.B AND B S

Pathology and Bacteriology, Materia Medica, Pharmacology and Pharmacy, Public Health Medical Jurisprudence—M J Arnott, T L Kelly, and H D Ord

Pathology and Bacteriology, Materia Medica, Pharmacology, General Principles of Therapeutics and Pharmacy, Public Health, Medical Jurisprudence—* Coley Goldstein, * J M. Tait and * H G Ungley, H M Brown, D S Buchanan, W C E Diamond

* With second-class honours

UNIVERSITY OF LIVERPOOL—Dr. W S Patton has been appointed to the Dutton Memorial Chair of Entomology.

At recent examinations the following candidates were successful —

Diploma in Tropical Medicine

C P Allen, M L Bahl, B Barrowman, J D Bilimoria, W M Burns E J Daly, G A Dunlop, V Dyream, M Farid, *A M Gillespie S A Gunawardana J Harkness, R Hay, N M Hodivala, Emma Hughes, Kathleen M. Hyslop, R E Ingram-Johnson J S Kapadia, J Macdonald, R S McElroy, W S Maclay, H G Maguire A F Mahaffy, A H Malhotra, H L Malhotra, B S Manghitmalani, J N Mehra, A J Murray, H M Nevin, N. T Olusoga, D B Parakh M R Peters, *R S Rao, S R A Shah, J F Southward Frances C Thompson, B J van de S de Villiers, and R Walkinshaw

* Recommended for the Milne Medal

Diploma in Tropical Hygiene

T A Austin, B Barrowman, W W. Beeson, J C St G Earl, J Hamilton, C F McCon, Winifred H Mitchell, R Nixon, W S Ormiston, and A Robertson

UNIVERSITY OF MANCHESTER—At a recent examination Dr T N Fisher was approved for the Certificate in School Hygiene

UNIVERSITY OF DUBLIN—At recent examinations the following candidates were successful:—

FINAL MEDICAL EXAMINATION—PART I

Therapeutics, Jurisprudence, Pathology, &c—D S P Wilson, H S Smithwick A G C Ffolliott, Kenneth Watson, William Crawford, R I G Reid, F R Falkner, J E M'Mahon, P A. Thornton, and W I Chapman In Completion J A Dowds, Izaak le Roux, E. du P Meiring, and J E Wells.

PART II

Medicine—*R A Q O'Meara, Maximilian Gerber, W F Lane, M F N Griffin R W T H Stewart, R S F Hennessey, G S Smyth, R D Whiteacre, C F Cope, Patrick Brangan, S D K Roberts, G O Taylor, E A Ellis, C L Day, N J U Mather Maurice Sherowitz, S B Dalrymple, S R. Elmes M G J Booysen Norah W Brown, W F Knobel, C de W Meintjes, A C C Charles, D M Carson, and H C Weir

Surgery—Solomon Behr, G O Taylor, G S Smyth, Solomon Gurevich P M Garry G D Edwards, M G J Booysen, Maurice Sherowitz, and R C U Warrington

Midwifery—*P M Garry *E M Gamble, T J Millin, Maximilian Gerber R M Moore J R Hanna Hyman Dundon, J M. M'Elligott I F Ratthaus and Izaak le Roux.

* Passed on high marks

DIPLOMA IN PUBLIC HEALTH

Part I—Meave Halligan, Brenda M Young Sarah M. Coghlan, J V M'Nally, Kathleen M Ball, Kathleen M Kennedy and Margaret E Pedlow

Part II—Anna M Allen

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS

Anne Siret, and Pritmila Mehta

MEDICAL INSPECTION OF SCHOOL-CHILDREN IN DUBLIN—It was announced last week that the Dublin City Commissioners have prepared a scheme for the inspection of school-children along lines suggested by the medical officer of health Two medical officers are to be appointed to act as school medical officer and assistant school medical officer respectively with the help of two nurses The salaries of the medical officers will be £700 rising by increments of £40 to £900 and £500 rising by increments of £20 to £700 It is intended that the school medical service be coördinated with the maternity and child welfare scheme, and this scheme will be put in the charge of the school medical officers

BRITISH ORTHOPÆDIC ASSOCIATION —The Robert Jones Medal and Prize offered by the Association for 1926 has not been awarded

ROYAL SOCIETY OF MEDICINE —The Society's house and library will be closed from Thursday, April 14th, to Tuesday, April 19th, both days inclusive

BRITISH SCIENCE GUILD —A dinner will be held at the Criterion Restaurant, London, on May 12th Particulars may be had from the Secretary, at 6, John-street, Adelphi, London W C 2

MEDICAL SOCIETY OF LONDON —At a meeting of this society held on March 28th the following were elected Honorary Fellows Prof Irving Cameron (Canada), Prof Sir Charles Scott Sherrington (Oxford), Prof H C Jacobaeus (Stockholm), and Prof K F Wenckebach (Vienna)

THE King of the Belgians has appointed Dr Clement Clapton Chesterman, to be a member of the Commission for the Protection of Natives in the Belgian Congo For the past eight years Dr Chesterman has worked for the Baptist Missionary Society in this colony and has been in charge of the Yakusu Hospital

CREMATION SOCIETY OF ENGLAND —The annual report of this Society shows a satisfactory financial position During the year 1926 2877 *cremations* were carried out at the 16 crematoria in Great Britain as compared with 2701 in the year 1925 Many improvements have been made at the various crematoria belonging to the Society, while a new building is now under construction in Arnos Vale Cemetery, Bristol, and the Guernsey States Committee have decided to erect a crematorium in that island The report records the progress of the cremation movement abroad, and closes with an appeal for public support, for "notwithstanding the Society's financial stability, its resources at present are inadequate to provide space and trained staff to deal with the rapidly increasing volume of business"

HOSPITALS FOR COUNTY CORK —When the health services throughout the Irish Free State were amalgamated a few years ago with county schemes most of the district hospitals were closed, and the hospital accommodation was concentrated into one or two hospitals in each county While this might work well enough in many of the small counties, in large counties, such as Galway or Cork, it put grave hardships on the sick poor of many areas This fault, in the case of Cork, is now to be remedied by the establishment of hospitals in no less than six additional centres—namely, district hospitals and fever hospitals at Macroom, Bantry and Skibbereen, district hospitals at Kanturk and Clonakilty, and a cottage hospital at Bandon At present there is a district hospital at Midleton a surgical hospital at Fermoy, and a district hospital at Youghal The calculated expenditure will be £100,000 Motor ambulances of an improved type have already been provided at Cork, Mallow, Fermoy, Clonakilty, and Skibbereen and ambulances will be provided for the new hospitals when built

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH —On March 22nd Dr N McLeod read a paper on abdominal pain and hyperalgesia He divided the causes of pain in intra-abdominal disorders into two main groups—mechanical and inflammatory In the first group were abnormal muscular movements of the gastro intestinal tube, and different types of pain might be experienced in disordered peristalsis as compared with exaggerated peristalsis He quoted cases of abdominal pain where such dragging on the peritoneum had occurred as a result of bands and adhesions but where the symptoms could only be explained as due to exaggerated muscular movements in the wall of the intestine There were also cases in which dragging or adhesions to parietal peritoneum could definitely be assumed but in which no symptoms arose In speaking of the inflammatory group Dr McLeod discussed the production and the localisation of pain in local peritonitis, visceral and parietal Apparently, he said, the viscero sensory reflex was similarly disturbed in both varieties, but in the case of parietal peritonitis there was an additional factor—namely, the involvement of the cerebro spinal nerve-endings in the extraperitoneal tissue by direct spread of inflammation He concluded that in cases in which visceral peritoneum alone was involved the symptoms were those referable to the organ which was covered by the inflamed peritoneum, whilst in local parietal peritonitis pain was localised over the area of peritoneum affected

A post-graduate course will be held by the James Mackenzie Institute at St Andrews from June 11th to 28th It will largely consist of lectures and demonstrations bearing on the recognition and treatment of disease in its early stages The fee will be £3 3s payable in advance to the Secretary, from whom further information may be obtained

LISTER CENTENARY EXHIBITS —A large collection of Lister relics was on view at the Wellcome Historical Medical Museum on April 4th and at an evening reception on the 7th An excellent handbook illustrates the exhibition

Dr Frances Margaret Harper, late assistant medical officer of health at St Helen's, is joining the medical staff at the hospital established in 1913 on the Ogowe River (French Equatorial Africa) by Dr Albert Schweitzer Dr Harper was attached to the 2nd Malta Company of the Royal Army Medical Corps during the late war, and in 1922 went out to the Baptist Mission Hospital at Bolobo in the Belgian Congo

DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.—At the annual meeting the position of this institution of 225 beds was reported to be desperate There is a debt of £20,000, the bank will lend no more because there are no further securities to offer, and the hospital site cannot be mortgaged because it was given by the Liverpool Corporation specifically for a hospital Pending the fruition of the contributory scheme that has been decided upon the Lord Mayor has undertaken to make a special appeal to the city and neighbourhood

TYPHOID FEVER IN MONTREAL —According to the City Health Department the total number of cases of typhoid fever in Montreal since March 1th has been 1510. About 25 per cent have sufficiently recovered to return to work Cases have now appeared at Quebec As a result of the Montreal epidemic, the United States laid an embargo on milk and cream imported from Canada The Canadian Government is endeavouring to have the embargo removed from districts which have not shipped milk and cream to the United States for six months Last year Canada exported milk and cream to the United States to the value of between £1,200,000 and £1,100,000

LIVERPOOL CHILD WELFARE ASSOCIATION —Some idea of the extensive and beneficent work of this association can be gained from the report which was presented at the annual meeting on March 31st During last year 5000 applications for assistance were granted, 32 310 parents were helped, 30,000 visits were paid to homes where help was needed, and 2509 children were sent from congested city areas into the country for periods varying from three weeks to six months In the infant welfare department there were 1308 attendances by expectant mothers, 22 011 by mothers and babies at the weekly consultations, and 331 at the new dental clinic The bank overdraft stands at over £11,000 Parents contributed £1087, mostly in small sums, to the funds of the association

BRITISH SOCIAL HYGIENE COUNCIL —An extraordinary general meeting of the Council was held on 30th March (at Carteret House, Mr E B Turner relieved later by Sir A Newsholme) in the chair Dr David Lees and Mrs C Neville Rolfe reported on their recent four months tour in India Dr Lees had he said, been shocked to find how prevalent syphilis was in India of the cases in one hospital in nine months, 30 per cent were syphilitic, and in a gynæcological clinic in which the blood of every patient was examined, 85 per cent were found to give a positive Wassermann reaction Directors of public health, hospital medical officers, in fact the whole profession, had proved most ready to help in every way, and in conferences of medical men, held in the provinces visited, the profession's demands were formulated for the better treatment of venereal disease, including out-patient clinics at every hospital, with beds set apart in teaching hospitals, antenatal beds in maternity hospitals, special treatment at child welfare centres, provision for the treatment of merchant seamen better teaching for students, opportunities for post-graduate instruction, the appointment of a specialist in venereal diseases on the surgical teaching staff of the Universities and free laboratory service to be provided available by the Government Mrs Rolfe related what had already been done The Government had agreed to grant recreation grounds for merchant seamen and they had asked for a physiological specialist to train head teachers next winter in the fundamentals of social hygiene, in order that they in turn might instruct the teachers in the provinces The delegates were congratulated on what they had secured

A summer school will be held at Keble College, Oxford, from August 3rd to 9th A course of lectures on biology and social hygiene will be given by Prof J Arthur Thomson, and a course on psychology and social hygiene by Dr H Crichton-Miller Applications for membership should be sent to the Secretary, at Carteret House, Carteret-street, London, S W 1

BOLINGBROKE HOSPITAL EXTENSION. — The "William Shepherd" Memorial Wing of this hospital at Wandsworth Common was opened on Monday last by Mrs. H Percy Shepherd wife of Mr. Sheriff Shepherd in whose father's memory it has been erected The Lord Mayor and the Lady Mayoress opened the new operating theatre and Lady Carmichael the new Children s Ward presented by her husband and herself, which will bear her name.

CARLISLE ROTARY CLUB —On March 30th an address on the Lister Centenary was delivered before this Club by Mr Norman Maclaren surgeon to the Cumberland Infirmary As recorded in the article reprinted on p 774 Lister visited Carlisle in 1864 as the guest of Dr. Robert Elliot first medical officer of the town in order to become personally acquainted with McDougall's antiseptic method of sewage treatment. That by adopting this method the town sanitary authorities had suggested to Lister the principles which he afterwards applied to the treatment of wounds, was a fact said Mr Maclaren, of which Carlisle might well be proud

A LEEDS POOR-LAW HOSPITAL. — The Leeds Guardians have approved an important scheme for extending the scope of hospital treatment at the Township Infirmary of 900 beds in Beckett-street. Consultants in aural surgery and gynæcology are to be appointed and will be paid three guineas a visit and five guineas for an operation. A radiologist will receive £250 a year whilst it is proposed to elect three surgeons and physicians at £300 a year, to include all operations and visits The resident staff will be increased to six assistant medical officers. the extra three to be advertised for at £200 a year. Paying patients are to be charged three guineas a week to cover all charges including operations

DONATIONS AND BEQUESTS —St. Mary s Hospital. Manchester have received the following legacies £1000 from the executors of the late Mr Anthony Willis £753 from the executors of the late Mr W H. Beverley and £744 from the executors of the late Mr J. Parr Mr L. John Poingdestre Hacquoil of Sambourne Sneyd Park Bristol shipowner and coal exporter of Cardiff left the residue of his estate after various legacies to his sister for life and on her death the ultimate residue—which will amount to about £10 000—to the Cardiff Royal Infirmary now known as King Edward VII. Hospital Mr John Readhead J P of Rockcliffe South Shields Durham left £1000 to the Ingham Infirmary and South Shields and Westoe Dispensary Mr Henry Jones Evans of Escuan Hall Towyn Merioneth left £1500 to the War Memorial Hospital Towyn

THE LATE DR A G WILKINS —Dr Arthur Godfrey Wilkins who died on March 9th in his fifty-first year was the son of the late Prof A S Wilkins of Manchester University He was educated at Sedbergh and at Owens College and graduated in medicine with honours in 1900 After holding several house appointments at Manchester and Salford he settled in practice in Patterdale. During the 12 years he stayed there he lost no chance of gaining experience *engaging a locum* he would go away from time to time to hospitals or on voyages abroad and in 1906 he was at Valparaiso during the earthquake On the outbreak of war he sold his practice and joined the French Service de Santé. When the age-limit was raised he was granted a commission in the Royal Army Medical Corps and served first at Wimereux and later in East Africa In 1918 he was nominated to the Egyptian Army but he never went to Egypt as the war ended soon after the appointment was made On his return to England Dr Wilkins s health was impaired and private practice was out of the question. He became school medical officer to the Staffordshire County Council and did admirable work in the establishment and administration of clinics. After 18 months however he resigned his appointment feeling that his organisation was as complete as he could make it. The next two years were spent in voyages as ship s surgeon to China and the East Indies On his return he held appointments at Prestwood and Market Drayton Sanatoriums His last post was that of medical superintendent of the Essex County Sanatorium where his ability as an administrator was generally recognised He had gained exceptionally wide experience largely as a result of visiting every hospital sanatorium cripples home asylum or clinic which it was possible to see in the course of his many travels in several continents During the war he made a special study of anæsthetics and became an exceptionally able anæsthetist He contributed to the literature of this subject. His health unfortunately proved unequal to the work at Harold Court and he retired to the Isle of Wight. Dr Wilkins leaves a widow

THE CHRONIC RHEUMATIC DISEASES*

By Carey F Coombs, M D, F R C P Lond,

PHYSICIAN WITH CHARGE OF OUT PATIENTS, BRISTOL GENERAL HOSPITAL.

(*Concluded from p 741*)

Non-articular Manifestations

We will now take a brief glance at that last part of this survey to which the Ministry of Health's report gave the name "Non-articular manifestations" In this group are included muscular rheumatism and lumbago, and sciatica and brachial neuritis To all these maladies the general term fibrositis is often applied It must be confessed that we have but little direct evidence to support the hypothesis that this title assumes—namely, that the essential change is an inflammation of the fibrous investments of the muscles, or the nerve trunks, or both That is the assumption, but there is little evidence, for the good reason that people never die of fibrositis and therefore give us little opportunity of seeing under the microscope exactly what it is that happens in an attack of lumbago or stiff neck. It is wonderful how little is known about disease of voluntary muscle I suppose the voluntary muscles are responsible for at least one tenth of the total body-weight, and yet less than one three-hundredth part of what may be regarded as the best modern text-book of medicine in our language is devoted to diseases of those same muscles

As a link between these muscular inflammations and the rheumatic infections of childhood, we ought to take note of the fact, that the pains of the rheumatic child arise in muscles nearly as often as they do in joints Stiff neck, for example, of an unmistakably muscular type may be accompanied in the child by fever and the development of heart disease, proving almost beyond controversy that the muscles of the neck have been invaded and irritated by bacteria Indeed, I have actually seen with the microscope patches of inflammatory reaction in the muscles surrounding the elbow-joint of a rheumatic child Similar inflammatory patches, almost certainly bacterial in origin, have been found in the muscles and intermuscular tissues of persons with fibrositis Moreover, even when there is no opportunity of seeing these patches they can sometimes be felt in the form of inflammatory nodules perceived by the fingers of the observer to lie in the depths of the muscles In sciatica, again, an inflammation of the fibrous sheath of the great sciatic nerve has actually been seen to occur There are, therefore, a number of odd scraps of evidence which justify the existence of that useful though etymologically indefensible term "fibrositis" This complaint that we are discussing muscular rheumatism, with its near relatives sciatica and brachial neuritis, proved to be the commonest of all the forms of rheumatic troubles investigated by the Ministry of Health Committee The figures of their report indicate that if we take a sample group of the insured population we shall find nearly 2 per cent of the men, and more than 1 per cent of the women disabled by complaints that it will be convenient to group together as "fibrositis" This brings graphically before us the new point of view in medicine Formerly the chief motive power of preventive medicine was pity for the sufferings of others Now, however, there is added to this a concern for our own pockets, out of which is taken the money on which these disabled persons are to live I must confess to a certain distaste for this motive, and prefer to assume that in our zeal for the abolition of fibrositis we are full of the best intentions, and prepared, for the sake of preventing suffering, to deprive countless spas, physiotherapeutic institutes, and liniment manufacturers of their means of livelihood

How to abolish Fibrositis

How are we going to set about it? In the first place, fibrositis is clearly a malady of maturity, as the Ministry of Health's figures show This is so generally recognised that even one of His Majesty's judges—who do not, as a rule, display their knowledge of medicine with any confidence—remarked the other day that we are all more or less rheumatic after 40 The influence of sex is curious and exhibits some cross currents Sciatica is commoner in men, brachial neuritis in women Some families are more liable to these complaints than others and occasionally this vulnerability appears, like that of the gouty family, to depend on a familial incapacity to utilise certain foodstuffs "One man's meat is another man's poison", and butcher's meat in general, beef in particular, appears to have a toxic effect on some individuals, an effect which may express itself in the form of muscular pains apparently of rheumatic type In some cases, again, these affections of the fibrous sheaths of muscles and nerves are actually and directly due to gout

---

* Lectures on the Causes and Prevention of Rheumatism delivered under the Chadwick Trust The first lecture appeared in two instalments in The Lancet of March 12th and 19th The second lecture (the first half of which appeared last week) was given on March 10th 1927

Such simple everyday influences as strain and chill play a part that cannot be denied in precipitating attacks of fibrositis In both cases it is to be presumed that what happens is the production of some small injury to a muscle or its fibrous sheath which gives to vagrant microbes a spot in which to settle and multiply In much the same way we may explain the action of fatigue, which may either precipitate the acute forms or perpetuate the chronic types of fibrositis

Another influence that cannot be denied is oral sepsis Here again we have to preserve our balance, but without doubt there is a connexion between the two In my own experience this connexion has appeared to be occasional, and not invariable as in the view of some It is so easy to advise the removal of teeth, but impossible to put them back again, and one's sense of proportion is outraged by wholesale extractions advised for the cure of something which they may fail even to relieve, something which is, after all, nothing more than an inconvenience in most cases

Further, the value of morale is seen nowhere, in time of peace, more plainly than in the reaction of different persons to the pains of muscular rheumatism, one might even say to all forms of chronic rheumatic pain At one end of the scale you have the woman who endures heroically the sufferings and limitations of a rheumatoid arthritis, refuses to be tied down to her chair or bed by it, and incidentally escapes the curse of excessive treatment She is often rewarded by an improvement in her condition, and, at worst, succeeds in enjoying life and maintaining her sense of well-being At the other end of the scale is the man who turns with no great reluctance from his work, at the first shock of muscular pain, either to his panel doctor for a certificate or to his spa for a pleasant holiday If we are out on an errand of mercy in our endeavour to prevent those painful maladies, we do well, but if it is merely an economic proposition, as much good might be done by directing our attention to the morale of the public as to its physique

A Review of the Position

And now we are in a position to look back on the whole field over which we have rapidly skimmed We have reviewed the various conditions that may legitimately be called rheumatic, and in a certain order chosen deliberately because it has passed from the known to the less known, from that which is dangerous to that which is serious, and so on to that which is merely inconvenient The diseases we have discussed overlap a good deal more than I have been able to show in so brief a review, both in their symptoms and in their causes For example, the division of these chronic forms of joint disease into rheumatoid arthritis is no more fundamental than a division of the white race into blondes and brunettes The boundary is not a sharp line, it is a blurred zone fading off gradually on either side towards the contrasting extremes Examples of joint disease are met with which represent every shade of combination of the qualities of osteo-arthritis at one end of the scale and rheumatoid arthritis at the other When the degenerative or senile factor is in the ascendancy, the result is a lesion of the joint that approximates to the osteo-arthritic type On the other hand, the more obvious the microbic influence the more nearly rheumatoid the lesion The relation between these two great subdivisions of chronic rheumatic disease is therefore very definite

But when we turn to those forms of *rheumatic disease* which affect muscles and nerve sheaths—conditions which we have agreed to include within the term "fibrositis"—there is far less reason to connect them with the joint troubles that we have just been discussing Only broadly may we say that the same influences that are responsible for troubling the joints are also often to be detected in the act of causing these muscular pains also Recent work has stressed the microbic element, to which I have already alluded, in the provocation of the various forms of fibrositis as well as in that of the chronic joint disorders of which I have spoken

Need of Organised Inquiry

Indeed, we are in some danger of coming to treat every one of these rheumatic disorders as the expression of what has been well named "subinfection", infection—that is, by micro organisms that do not ordinarily succeed in doing any damage, though they are continually present on the mucous surfaces of the body That this "*subinfection*" does, indeed, play its part in all forms of rheumatic trouble is almost certainly true, and the recognition of this marks a great step forward But it is obvious to everyone that it is by no means the whole truth For, if all these maladies are merely expressions of the fact that organisms of a low virulence have got into our joints and muscles, how is it that in one patient the result is a rheumatoid arthritis, in another, sciatica? It is clear that between the spot at which the microbe enters the body, and the site of the crippling that it produces, a whole host of causal agents must come into play, differing in one person from those of another, as heredity and environment differ Somehow or other we have to study these influences and disentangle them from one another This is so hard a task that we cannot wonder at its unpopularity It is so much easier to say that the disease is due to septic teeth, and to have those teeth removed, especially when they happen to be someone else's teeth It is here that the inquiry made by the Ministry of Health shows us a more excellent way, and it is much to be hoped that the example which it has set, of voluntary coöperation between a number of doctors in study of the causes of the rheumatic group of diseases, will be imitated and elaborated The organisation of such work as this is no light matter It demands a combination of enthusiasm with patience which is not always to be found Yet I believe we have come to a point in the war against disease beyond which it is impossible to progress except by united action, into which the several branches of our profession may be led but not driven, persuaded but not dragooned It is possible that when all has been done, and every kind of chronic rheumatic trouble subjected to a minute analysis it will lead to nothing but the simplest and most elementary conclusions It may even reduce the campaign for the prevention of chronic rheumatic disease to nothing more dignified than a restatement of Longfellow's couplet —

> "Joy and Temperance and Repose
> Slam the door on the doctor's nose"

The fact is, that thanks largely to the labours of Sir Edwin Chadwick and his associates, we are no longer facing the same enemies as he did The shock troops of disease, the bacteria of typhus, plague, cholera, and the like, have made their attack and been thrown back in disorder Now we have a different kind of enemy, the saprophytic micro-organisms who infest the normal body These have settled down to a long war, a war of attrition, on which we must bring to bear the same principles that have won such signal victories over acute disease We saw at the beginning of this address that as against the acute infections, so also against these chronic rheumatic diseases, the campaign opened with a classification of the various kinds of disease based on discrimination between their symptoms After this comes inquiry into the respective causes of the different groups So far as the chronic rheumatic diseases are concerned we are still in that stage As the knowledge of these causes is gained, bit by bit, so it will be diffused, and in the end it is by the spread of knowledge of causes that disease is prevented

---

A SCHEME FOR COPING WITH INFLUENZA EPIDEMICS

OWING to the serious character of the influenza epidemic in South Africa in 1918, the Union health authorities have recommended that precautions should be taken to prevent a similar occurrence following on the present European epidemic Our South African correspondent has informed us that several of the municipalities have set out schemes of procedure, the details of one of these schemes deserves attention

In Cape Town members of the local branch of the Medical Association of South Africa, the St John Ambulance Association, South African Trained Nurses' Association, Royal Automobile Club, Women's Municipal Association, Boy Scouts, Girl Guides, and other kindred bodies have been asked to coöperate in organising medical and other services in the city in the event of an outbreak of influenza The Council of the Cape Western Branch of the Medical Association of South Africa (B M A.), have recommended the following measures —

Organisation of Medical Profession —It has been arranged for an organising medical secretary to prepare in detail the following scheme (*a*) the subdivison of the municipal area into districts, (*b*) the appointment of a medical commandant for each district, (*c*) the collaboration of medical men in each district with its respective commandant, (*d*) a roster of emergency medical men, drawn from specialists, retired doctors, medical students, &c, for emergency work in districts reported by commandants as requiring assistance, (*e*) methods of communication between depôts arranged by the City Health Service and the commandants for the supply of nursing service, guides, drugs food, &c The organising medical secretary would be, with his organisation, at the service of the medical officer of health

Publicity —The following avenues of reaching the public were recommended (*a*) the Press and the medical association to coöperate with the City Council in publicity measures

Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Great Barrow —Asst M O £250
Chester Royal Infirmary —H S £150
Chesterfield and North Derbyshire Royal Hospital —Hon Ophth S
Derbyshire, Royal Infirmary, Derby —H P and Asst H S , and Cas O Each at rate of £150
East London Hospital for Children and Dispensary for Women, Shadwell E —H P H S and Cas O Each at rate of £125
Exeter, Royal Devon and Exeter Hospital,—Res Cas O At rate of £100
Gloucester, Standish House Sanatorium, Stonehouse —Asst M.O £250
Guildford Royal Surrey County Hospital —H S £150
Halifax Royal Infirmary —Third H S At rate of £100
Hampstead General and North West London Hospital, Haverstock Hill N W —H S H P , and Cas M O Each at rate of £100
His Majesty s Indian Medical Service —Commissions
Hospital for Consumption and Diseases of Chest, Brompton, S W —H P
Infants Hospital, Vincent square, Westminster —Pathologist £600
Ipswich, East Suffolk and Ipswich Hospital —H S , for Ear, Throat and Nose Dept £100
Jerusalem Ophthalmic Hospital —Sub-Warden Also Registrar
Kent Education Committee, School Medical Service —Dental S £500
Lancaster Borough —Asst M O H , &c £500
Leeds Gateforth Sanatorium —Res M O £400
Leigh Infirmary, Leigh Lancashire —Res H S £150
London Hospital Dental School, Mile End, E —Demonstrator £200
London Hospital E —P to Skin Dept
Maidstone, Kent County Mental Hospital —Asst M O £300
Manchester Ancoats Hospital —H S for Orthopædic Dept At rate of £100
Manchester City —Asst Tuberculosis O £600
Manchester, County Mental Hospital, Prestwich —Asst M O £350 to £450
Middlesex County Council Dental Service —Asst Dental O £500
Miller General Hospital for South-East London, Greenwich road, S E —Out patient O £150
Norwich, Norfolk and Norwich Hospital —H S £120
Portsmouth, Royal Hospital —Cas O At rate of £100
Preston Lancs , County Mental Hospital, Whittingham —Sixth Asst M O £350
Prince of Wales's General Hospital , Tottenham, N —Two Hon Anæsthetists Each £40
Public Dispensary, 122, Drury Lane, W C —Res M O £105
Putney Hospital, Lower Common, Putney, S W —Res M O £150
Reading, Royal Berkshire Hospital —H S £150
Rochester, St Bartholomew's Hospital —Third Res M O At rate of £175
Royal Chest Hospital, City road, E C —H P At rate of £100 Also Res M O At rate of £150
Royal College of Surgeons of England —Examiners
Royal Northern Hospital Holloway, N —H S At rate of £70
Royal Waterloo Hospital for Children and Women, Waterloo road, S E —Non Res Cas O £150
Sheffield Royal Hospital —Res H P At rate of £80
Stockton on Tees, Stockton and Thornaby Hospital —Hon S to Ear, Nose and Throat Dept
Tunbridge Wells and Counties General Hospital —H S £160
Ventnor, Isle of Wight, Royal National Hospital for Consumption —Med Supt £1000
West End Hospital for Nervous Diseases, 73, Welbeck-street, W —Cas P £200
West Ham County Borough —Asst M O and Maternity and Child Welfare £600

Births, Marriages, and Deaths.

BIRTHS

COLDREY —On March 28th, at Chatham House, Rotherham, Yorks, the wife of Eric Coldrey, M D , F R C S of a son

FULLER —On April 1st at St Michael's Lodge, Winchester, the wife of C B S Fuller, M C , M D , M R C P , of a son

MARRIAGES

MACKAY—MACDONALD —On March 25th, in London, George W M Mackay, M A , M B , Ch B , to Catherine E S Macdonald

MARTIN WARD —On April 2nd, 1927, at St Thomas Church Belfast, by the Very Reverend the Dean of Connor, Alexander Reid Martin, M B , B Ch Belf , D P M Lond of Sheppard and Enoch Pratt Hospital Baltimore U S A , son of Mrs C R Martin, Wilmont-terrace Belfast to Nancy daughter of the late John K Ward and Mrs M J Ward, University street, Belfast

MILLS—GOODING —On March 31st, 1927; at St Thomas of Canterbury, Woodford Wells by the Rev Fr Isidore McCann O F M , John Mills M B Ch B only son of Mrs S E Mills of St Annes on Sea Lancs , to Rita Gooding daughter of Mr and Mrs F C Gooding of Buckhurst Hill, Essex

DEATHS

MACEWAN —On March 31st, at his residence 2, Airlie Place, Dundee, David MacEwan, M D , C M , LL D , Emeritus, Professor of Surgery, University College, Dundee, in his 81st year

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Comments, and Abstracts.

THE CHRONIC RHEUMATIC DISEASES[*]

BY CAREY F COOMBS, M D , F R C P LOND,
PHYSICIAN WITH CHARGE OF OUT PATIENTS, BRISTOL GENERAL HOSPITAL.

(Concluded from p 741)

Non-articular Manifestations

WE will now take a brief glance at that last part of this survey to which the Ministry of Health's report gave the name " Non-articular manifestations " In this group are included muscular rheumatism and lumbago, and sciatica and brachial neuritis To all these maladies the general term fibrositis is often applied It must be confessed that we have but little direct evidence to support the hypothesis that this title assumes—namely, that the essential change is an inflammation of the fibrous investments of the muscles, or the nerve trunks, or both That is the assumption, but there is little evidence, for the good reason that people never die of fibrositis and therefore give us little opportunity of seeing under the microscope exactly what it is that happens in an attack of lumbago or stiff neck It is wonderful how little is known about disease of voluntary muscle I suppose the voluntary muscles are responsible for at least one-tenth of the total body-weight, and yet less than one three-hundredth part of what may be regarded as the best modern text-book of medicine in our language is devoted to diseases of those same muscles

As a link between these muscular inflammations and the rheumatic infections of childhood, we ought to take note of the fact, that the pains of the rheumatic child arise in muscles nearly as often as they do in joints Stiff neck, for example, of an unmistakably muscular type may be accompanied in the child by fever and the development of heart disease, proving almost beyond controversy that the muscles of the neck have been invaded and irritated by bacteria Indeed, I have actually seen with the microscope patches of inflammatory reaction in the muscles surrounding the elbow-joint of a rheumatic child Similar inflammatory patches, almost certainly bacterial in origin, have been found in the muscles and intermuscular tissues of persons with fibrositis Moreover, even when there is no opportunity of seeing these patches they can sometimes be felt in the form of inflammatory nodules perceived by the fingers of the observer to lie in the depths of the muscles In sciatica again, an inflammation of the fibrous sheath of the great sciatic nerve has actually been seen to occur There are, therefore, a number of odd scraps of evidence which justify the existence of that useful though etymologically indefensible term " fibrositis " This complaint that we are discussing, muscular rheumatism, with its near relatives sciatica and brachial neuritis, proved to be the commonest of all the forms of rheumatic troubles investigated by the Ministry of Health Committee The figures of their report indicate that if we take a sample group of the insured population we shall find nearly 2 per cent. of the men, and more than 1 per cent of the women disabled by complaints that it will be convenient to group together as " fibrositis " This brings graphically before us the new point of view in medicine Formerly the chief motive power of preventive medicine was pity for the sufferings of others Now, however, there is added to this a concern for our own pockets, out of which is taken the money on which these disabled persons are to live I must confess to a certain distaste for this motive, and prefer to assume that in our zeal for the abolition of fibrositis we are full of the best intentions, and prepared, for the sake of preventing suffering, to deprive countless spas, physiotherapeutic institutes, and liniment manufacturers of their means of livelihood

How to abolish Fibrositis

How are we going to set about it? In the first place, fibrositis is clearly a malady of maturity, as the Ministry of Health's figures show This is so generally recognised that even one of His Majesty s judges—who do not, as a rule, display their knowledge of medicine with any confidence—remarked the other day that we are all more or less rheumatic after 40 The influence of sex is curious and exhibits some cross currents Sciatica is commoner in men, brachial neuritis in women Some families are more liable to these complaints than others, and occasionally this vulnerability appears, like that of the gouty family, to depend on a familial incapacity to utilise certain foodstuffs "One man's meat is another man's poison", and butcher's meat in general, beef in particular, appears to have a toxic effect on some individuals, an effect which may express itself in the form of muscular pains apparently of rheumatic type In some cases, again, these affections of the fibrous sheaths of muscles and nerves are actually and directly due to gout

Births, Marriages, and Deaths.

BIRTHS

COLDREY —On March 28th, at Chatham House Rotherham, Yorks, the wife of Eric Coldrey, M D, F R C S, of a son

FULLER —On April 1st at St Michael's Lodge, Winchester, the wife of C B S Fuller, M C, M D, M R C P, of a son

MARRIAGES

MACKAY—MACDONALD —On March 25th, in London, George W M Mackay, M A, M B, Ch B, to Catherine E S Macdonald

MARTIN-WARD —On April 2nd, 1927, at St Thomas Church Belfast, by the Very Reverend the Dean of Connor, Alexander Reid Martin, M B B Ch Belf, D P M Lond of Sheppard and Enoch Pratt Hospital, Baltimore U S A, son of Mrs C R Martin, Wilmont-terrace, Belfast to Nancy daughter of the late John K Ward and Mrs M J Ward, University-street Belfast

MILLS—GOODING —On March 31st, 1927, at St Thomas of Canterbury, Woodford Wells by the Rev Fr Isidore McCann O F M, John Mills M B Ch B only son of Mrs S E Mills of St Annes on Sea Lancs, to Rita Gooding, daughter of Mr and Mrs F C Gooding of Buckhurst Hill, Essex

DEATHS

MACEWAN —On March 31st, at his residence 2, Airlie Place, Dundee, David MacEwan, M D, C M LL D Emeritus, Professor of Surgery, University College, Dundee, in his 81st year

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Comments, and Abstracts.

THE CHRONIC RHEUMATIC DISEASES*

BY CAREY F. COOMBS, M D, F R C P LOND,

PHYSICIAN WITH CHARGE OF OUT PATIENTS, BRISTOL GENERAL HOSPITAL.

(Concluded from p 741)

Non-articular Manifestations

WE will now take a brief glance at that last part of this survey to which the Ministry of Health's report gave the name "Non-articular manifestations" In this group are included muscular rheumatism and lumbago, and sciatica and brachial neuritis To all these maladies the general term fibrositis is often applied It must be confessed that we have but little direct evidence to support the hypothesis that this title assumes—namely, that the essential change is an inflammation of the fibrous investments of the muscles, or the nerve trunks, or both That is the assumption, but there is little evidence, for the good reason that people never die of fibrositis and therefore give us little opportunity of seeing under the microscope exactly what it is that happens in an attack of lumbago or stiff neck It is wonderful how little is known about disease of voluntary muscle I suppose the voluntary muscles are responsible for at least one-tenth of the total body-weight, and yet less than one three-hundredth part of what may be regarded as the best modern text-book of medicine in our language is devoted to diseases of those same muscles

As a link between these muscular inflammations and the rheumatic infections of childhood, we ought to take note of the fact, that the pains of the rheumatic child arise in muscles nearly as often as they do in joints Stiff neck, for example, of an unmistakably muscular type may be accompanied in the child by fever and the development of heart disease, proving almost beyond controversy that the muscles of the neck have been invaded and irritated by bacteria Indeed, I have actually seen with the microscope patches of inflammatory reaction in the muscles surrounding the elbow-joint of a rheumatic child Similar inflammatory patches, almost certainly bacterial in origin, have been found in the muscles and intermuscular tissues of persons with fibrositis Moreover, even when there is no opportunity of seeing these patches they can sometimes be felt in the form of inflammatory nodules perceived by the fingers of the observer to lie in the depths of the muscles In sciatica again, an inflammation of the fibrous sheath of the great sciatic nerve has actually been seen to occur There are, therefore, a number of odd scraps of evidence which justify the existence of that useful though etymologically indefensible term "fibrositis" This complaint that we are discussing muscular rheumatism, with its near relatives sciatica and brachial neuritis, proved to be the commonest of all the forms of rheumatic troubles investigated by the Ministry of Health Committee The figures of their report indicate that if we take a sample group of the insured population we shall find nearly 2 per cent of the men, and more than 1 per cent of the women disabled by complaints that it will be convenient to group together as "fibrositis" This brings graphically before us the new point of view in medicine Formerly the chief motive power of preventive medicine was pity for the sufferings of others Now, however, there is added to this a concern for our own pockets, out of which is taken the money on which these disabled persons are to live I must confess to a certain distaste for this motive, and prefer to assume that in our zeal for the abolition of fibrositis we are full of the best intentions, and prepared, for the sake of preventing suffering, to deprive countless spas physiotherapeutic institutes, and liniment manufacturers of their means of livelihood

How to abolish Fibrositis

How are we going to set about it? In the first place, fibrositis is clearly a malady of maturity, as the Ministry of Health's figures show This is so generally recognised that even one of His Majesty's judges—who do not, as a rule, display their knowledge of medicine with any confidence—remarked the other day that we are all more or less rheumatic after 40 The influence of sex is curious and exhibits some cross currents Sciatica is commoner in men, brachial neuritis in women Some families are more liable to these complaints than others and occasionally this vulnerability appears, like that of the gouty family, to depend on a

* Lectures on the Causes and Prevention of Rheumatism delivered under the Chadwick Trust The first lecture appeared in two instalments in THE LANCET of March 12th and 19th The second lecture (the first half of which appeared last week) was given on March 10th 1927

Hunterian Lecture

ON THE

PATHOLOGY AND TREATMENT OF THE RETAINED TESTIS IN CHILDHOOD.

Delivered before the Royal College of Surgeons of England on Feb. 18th, 1927,

By A. H. SOUTHAM, M.D., M.Ch. Oxf., F.R.C.S. Eng.,
HUNTERIAN PROFESSOR OF SURGERY, ROYAL COLLEGE OF SURGEONS OF ENGLAND,
AND
E. R. A. COOPER, M.D., M.Sc. Manch.,
DEMONSTRATOR OF ANATOMY IN THE UNIVERSITY OF MANCHESTER.

In selecting a subject for a lecture in commemoration of John Hunter none is more appropriate than the question of retention of the testis. This problem was one of profound interest to Hunter, and it need hardly be recalled that in 1786 he published his classical work on the "Situation of the Testis in the Fœtus with its Descent into the Scrotum." In this treatise he wrote: "The descent of the testicle is very slow which is not completed before birth, often requiring years for that purpose, and it sometimes never reaches the scrotum, especially the lower part of it. It sometimes happens that one of the testicles remains in the cavity of the abdomen through life, never changing its situation. When one or both testicles remain through life in the belly I believe they are exceedingly imperfect, and probably incapable of performing their natural functions, and that this imperfection prevents the disposition for descent taking place." In spite of the large amount of research in this direction, it is remarkable to find that little has been added to Hunter's observations on the phenomenon of testicular descent. His teachings on this problem, as on many others, have stood the test of time. There has been, however, considerable controversy regarding the condition of the retained testis which Hunter believed to be "exceedingly imperfect." Without referring to the various controversial aspects, it is hoped in this lecture to show that such a testis is *not necessarily* imperfect, and that any serious alterations in its condition are secondary, depending on the persistence of the malposition. Should this prove to be the case, then it is surmised that operative completion of the anatomical descent of the testis, before the intervention of secondary changes, will enable the gland to pursue its normal development.

The condition of retention of the testis was recognised long before Hunter gave the subject prominence in his "Treatise on Animal Œconomy" in 1786. It is said that Tamerlane, the conqueror of Western Asia during the fourteenth century, was afflicted with the deformity. Reference was made to the anomaly in the writings of Paré, Meibomius, and Salmuth; Haller, in 1755, in his "Opuscula Pathologica" described the intra-abdominal origin of the testis, and the descent into the scrotum during intra-uterine life. During the nineteenth century Lockwood emphasised Hunter's beliefs regarding the importance of the gubernaculum in the descent of the testis; whilst in 1851 Lecompte noted the predisposition of the misplaced organ to malignant degeneration. The first recorded operation to correct the malposition of a retained testis appears to have been performed by Koch of Munich in 1820.

Statistics show that anomalies of migration of the testis are not infrequent, true retention of the organ being perhaps the most common of these deformities. It has been stated by Wrisberg that 30 per cent. of newly born infants suffer from incomplete descent of one or both testes, though it is believed that the greater number of these organs reach the scrotum spontaneously during the first few weeks of life. It is difficult to estimate accurately the incidence of retention amongst the general male population. In consequence the rather limited figures from hospital admissions and army recruits will be quoted as the most convenient.

Of 10,000 recruits examined by a recruiting board in Scotland in 1916–17, unilateral or bilateral cryptorchidism was present in 52 individuals, an incidence of 5 cases per 1000. Hempel found 2 cases per 1000 were so affected in 7,000,000 Austrian recruits; while figures obtained from the American War Department in 1920 estimated the occurrence of this deformity at 3·1 per 1000. At the Manchester Royal Infirmary during a period of 15 years, amongst 57,000 male surgical admissions, there were 409 cases of retained testis—that is, 7 per 1000.

The association of some anomaly of testicular descent with hernia is not a rare occurrence. Mixter of Boston, has stated that mal-descent of the testis was present in 7·1 per cent. of cases of hernia in children. Coley has estimated the incidence at 3 per cent. At the Royal Manchester Children's Hospital cryptorchidism was found to be present in 9 per cent. of cases of inguinal hernia. In general, as far as these statistics permit, it may be stated that unilateral or bilateral cryptorchidism occurs roughly in 5 subjects per 1000; and the condition is often associated with a hernia of the inguinal type. The occurrence of retention of the testis seems, then, to be of sufficient frequency, apart from complications, to warrant serious consideration directed towards its correction.

There still exists a wide variance in the opinions of surgeons as to the best way of treating this deformity, and many pathologists are doubtful as to the functional capacity of a retained testis. Whilst it is true that the condition may cause little trouble during childhood, it may be a source of considerable irritation to the individual in later life. This results not only from the abnormal anatomical position of the organ, but also from secondary complications, and doubt as to its ability to function.

I propose first to give a short account of the mechanism of the descent of the testis, and to mention the function of the gland; secondly, the anatomical and histological structure of the normal and retained organs will be compared; and lastly, the question of treatment is to be considered and a description given of the anatomical results obtained in 50 cases which have been under observation during the past five years. The series under consideration are all cases of true retention of the testis—that is to say, a congenital, anatomical defect, where the testis, descending in its normal path, has failed to reach the scrotum. No case of ectopia testis, where the organ deviates from its usual route, has been included.

THE MECHANISM OF DESCENT OF THE TESTIS

The testes in man are developed as intra-abdominal organs close to the primitive kidneys, and during intra-uterine life they descend along the posterior abdominal wall, through the inguinal canal to the scrotum. Hunter pointed out that the mechanism, whereby the testes reach the scrotum, may sometimes fail, and the organs are then arrested at some intermediate point in their path of descent. In the early embryo the testis is attached to the posterior abdominal wall by a fold of peritoneum known as the mesorchium. Through the upper part of this fold the blood vessels pass to or from the gland. Fixed to the lower end of the mesorchium is the gubernaculum, an actively growing mass of fibro-muscular tissue. The gubernaculum grows downwards and draws with it the posterior parietal peritoneum which forms a closed pouch, the processus vaginalis. At the same time the gubernaculum pulls on the testis through the intermediation of the mesorchium.

When the growing gubernacular bud approaches the groin it initiates an evagination of the strata of the anterior abdominal wall. Still anchored to the processus vaginalis and the testis, it passes through the evagination and becomes attached to the redundant pouch of integument forming the scrotum. Thus the inguinal canal, processus vaginalis, and at the discretion of the medical officer of health, (*b*) Public lectures It is suggested that public lectures be given by the medical officer of health, and others (*c*) The broadcasting of such lectures should be arranged (*d*) The general contents of leaflets have been discussed and agreed upon by the council (*e*) The coöperation of teachers to be asked in distributing advice In view of the impossibility of forecasting the extent and duration of any epidemic, it was decided to draw up no hard-and-fast scheme of propaganda, but to use the above as exigencies demanded

Drugs —Formulæ to be known as aperient, febrifuge, and expectorant have been adopted for extreme emergency use The formulæ have been so drawn as to ensure chemists having no difficulty in obtaining the necessary ingredients A suitable vaccine for use as a prophylactic in influenza should be available The Council of the Cape Western Branch concludes the memorandum by assuring the City Council of its hearty coöperation, and its willingness to discuss any further measures in which the City Council considers it may be of assistance

Organisation of Trained Nurses —Representatives of the Trained Nurses Association have reported that a list could be prepared of members who were not actually employed in hospitals or private practice, and who would be available to assist at temporary hospitals They suggest that in case of emergency it would be well if trained nurses could be allotted from the hospitals by the Cape Hospital Board as an emergency measure until such time as the other members are ready to take their place In regard to partly trained nurses (by which they meant members of the St John Ambulance Brigade, Ambulance and Nursing Divisions), lists were available, and it was proposed to ascertain further the names and addresses of those V A D 's who had returned from military service but were not attached to the St John Ambulance organisation It was also recommended that house-to-house visitation should be carried out under the control of district nurses, assisted by V A D 's and untrained voluntary helpers, and it was urged upon the Health Authorities to support an increase in the number of district nurses throughout the Peninsula

OCCUPATIONAL ANALYSIS

THE principle of vocational selection is being more and more extensively adopted by manufacturers as the most logical way of increasing the efficiency of their staff Each applicant for work, in the organisations which have adopted the principle, is subjected to a psychological test to discover the direction in which his capabilities lie, so that he may be allotted to the task for which he is most fitted The supplementary principle of vocational guidance is also gaining ground, and many local educational authorities are actively superintending their pupils' absorption into industry Both selection and guidance must, however, depend on an accurate knowledge of the available occupations in terms of the demands they make on human physique and temperament and the study of the worker has undoubtedly outstripped the study of the work Detailed psychological descriptions of industrial processes have been practically unobtainable, and advisers have either made their own researches into a few of the industries with which they were most concerned, or have relied on the very crude material which has hitherto been at their disposal The National Institute of Industrial Psychology has now for some time been experimenting with a view to meeting this demand, and in the first report [1] of their vocational section they illustrate with full instructions and specimens a scheme by which information on the myriad existing industrial processes can be standardised Given a satisfactory standard form and notation it will be comparatively easy to form a pool to which advisers will be constantly adding and from which in time everyone will be able to draw the information he wants As an illustration of their thoroughness may be taken the sample on laundry work This industry is divided into eight processes collecting, receiving, sorting washing calendering ironing, packing, and delivery Form A, a broad description of the occupation, contains general information and notes on the special features, for instance—Prospects "At eighteen or earlier the girl is given an opportunity to learn hand ironing under a skilled worker It takes a girl from one to three months to reach proficiency Some laundries have regular training schools Prospect of promotion is fair for the more skilled classes of worker, including fine ironers and machinists from whom the forewomen are recruited " Each process is described on a separate form A calender, for example, is a machine which dries and irons in one operation and of a calender feeder the following psychological qualification is demanded "Manual skill chief hand and arm movement is $t_2 f_2^{1\,2\,3}$ Se, R & L (i e thumb and first three fingers of both hands are employed in gripping , arms are bent and elbows free) Touch control Also elbow movement similar to that of press work Accuracy of large movement C Speed C+ Temperament calm equable, no objections to monotonous work Experience " Armed with this report, a vocational adviser will be able to repair to a factory or workshop and obtain exactly the information he requires in the shortest possible time, and will have a common language in which he may read the experience of any other adviser The pamphlet marks a great step forward in the application of psychological knowledge to industry

ARSENIC AND APPLES

THE following is quoted from a letter written by the Acting Secretary of the United States Department of Agriculture at Washington, in answer to a communication from the London Vegetarian Society asking whether anything is now being done by American fruit growers to prevent the contamination of apples by arsenic [Vide THE LANCET, 1926 i 824, and ii , 81]

"Intensive studies designed to control the spray residue on fruit were made during the last producing season by both Governmental and commercial agencies While a great improvement in the condition of the crop was brought about it was found that in certain areas of low rainfall even the most careful restriction in the application of sprays, followed by brushing and wiping the fruit after harvest, left excessive quantities of residue on the fruit This demonstrated clearly the necessity for employing other methods of removing spray residues than by brushing or wiping Experimental work conducted last season in a number of localities where spray residue may be excessive at the time of harvest has shown that by the employment of certain dipping methods the fruit may be cleaned to a point where the amount of residue will be well below the recognised tolerance Steps are now being taken to advise the fruit producing industry in those regions where fruit cleaning is essential, of the equipment and processes necessary in the application of these different methods and everything possible will be done to bring about the installation of this equipment before the next packing season It is expected that as a result of the combined effort of the fruit producing industry and interested governmental agencies none of the fruit exported to Great Britain during the coming season will bear objectionable quantities of spray residue"

The full text of the letter is being published in the *Vegetarian News* for April

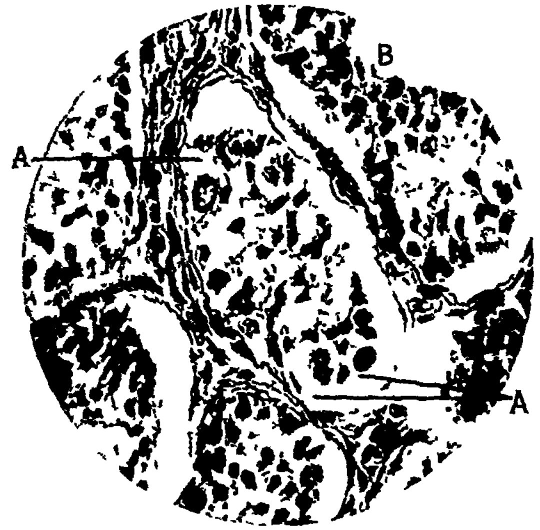
SOLLUX PAPERS ON U V THERAPY

THE Sollux Publishing Company have issued a collection of papers by well-known German writers dealing with ultra-violet therapy Some of them have been published before and the theories advanced may not fully represent the writers' present views , as working hypotheses, however, they are still valid Dr Hans L Heusner is opposed to the view generally held in this country that U V rays are to be avoided in pulmonary tubercle An analysis of 80 replies in response to a questionnaire which he circulated convinced him that there were "practically no unfavourable results " though in many cases improvement might have been slight U V treatment in phthisis has analogies with tuberculin treatment and demands a similar degree of caution , no good can be expected from massive doses and all exposures should be under the personal supervision of the physician in charge Heusner expresses the hope that, as a result of improved U V treatment of early cases the sanatoria may be reserved for the more advanced cases with positive sputum Hugo Bach testifies to the value of U V rays from whatever source in the treatment of war wounds, particularly when septic , he describes their disinfectant, deodorising, and drying effect and attributes these properties to local stimulation as well as to a general increase of metabolism The reprint of Huldschinsky's well-known paper on U V treatment of rickets contains abundant proof of the value of the rays in combating the severe post-war rickets amongst the children of Central Europe It is perhaps going too far to suggest that every child, whether showing signs of vitamin deficiency or not should be given U V treatment in infancy as a matter of routine Of a more speculative nature are the papers by Profs G A Rost and A Jesionek After pointing out the fallacy of Finsen's original idea of a direct action of U V rays on the tubercle bacilli in lupoid tissues, Rost suggests that the effect is due to "primary " and "secondary" tissue reactions in response to the absorbed radiation In disagreement with Rollier and Jesionek, Rost is against the development of pigmentation as a desirable sign of progress under U V treatment, and while not disputing the excellent results obtained in many patients who pigment, considers that equally good or better results can be obtained without pushing dosage to the point of pigmentation, a process which he regards as a natural defence against the penetration of the U V rays Erythema, on the other hand he regards as essential to treatment and, as pigmentation is preceded in most cases by marked erythema he finds therein the explanation of the good results reported with pigmenting doses plasm. One to four spermatogonia were present in each tubule. They consisted of a very large, spherical, deeply-stained nucleus with distinct peripheral chromatin spots, and a large well-defined cell body of clear protoplasm

---

[1] Institute Report, No 1, 329, High Holborn, London, W C 2s

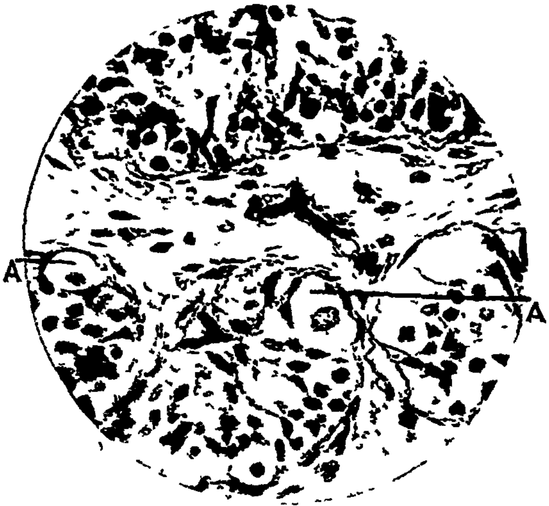
FIG 2



Section of scrotal testis, aged 10 months A, Spermatogonia B, Undifferentiated cells 23 × 400

About the tenth year a further differentiation of the undifferentiated cells occurred The nuclei appeared to have lost their innumerable chromatin spots which were replaced by one or two definite nucleoli These cells then came to resemble those described as true cells of Sertoli This differentiation continued throughout puberty and was accompanied from about the twelfth year *onwards* by mitotic changes in the spermatogonia, fully formed spermatozoa being recognised about the *fourteenth* year

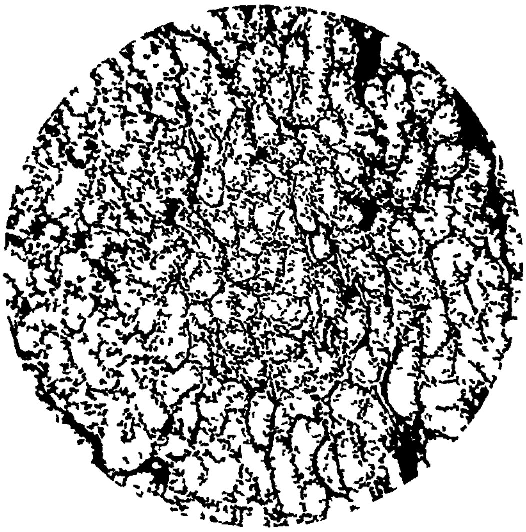
FIG 4.



Section of testis, aged 13 years, retained in lower part of inguinal canal A, Spermatogonia 3 × 400

It is significant to notice, however, that great variation occurred in the date of onset of spermatogenesis, and that in spite of adolescent age a scrotal testis frequently presented a preadolescent histological structure The interstitial cells of Leydig were found to be in large numbers during *fœtal* life and until the fourth month after birth occupying the wide intertubular intervals After that age they remained in abeyance until the twelfth year, when they reappeared in the small intertubular angles and persisted throughout puberty in what was presumably *an active condition. It* was remarkable to find that between these two ages few or no cells with any resemblance to cells of Leydig could be distinguished in the interstitial tissue.

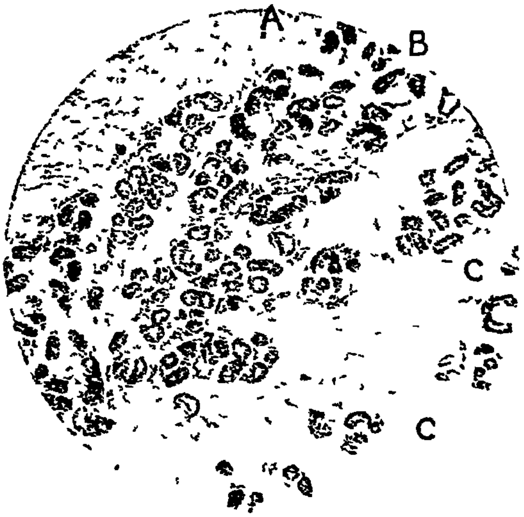
FIG 3



Section of testis, aged 14 months, retained in lower part of inguinal canal showing closely packed tubules 22 × 60

Turning now to the retained testes, mention has already been made of the variation in size. An interesting feature in these glands was the high percentage of cases presenting a wide separation of the testis and epididymis (Fig 1 (A)), but this condition was not peculiar to the retained organ

FIG 5



Section of testis, aged 13 years, retained in abdomen A, Tunica albuginea B, Peripheral tubules C, Fibrous tissue occupying centre of gland 4 × 35

Three testes examined were retained in the inguinal canal near the external abdominal ring Two of these, from children aged 14 months and 13 years respectively, lay just internal to the external ring, whilst the third, from a subject of 60 years, was situated *in* the ring which was considerably enlarged by the scrotum are formed in advance of the descending testis The subsequent shortening of the gubernaculum and its firm attachment to the bottom of the scrotum are said to be instrumental in bringing the testis into its ultimate scrotal position It must be borne in mind, however, that arrest of further growth of the gubernaculum, after becoming attached to the scrotum, together with normal growth of surrounding structures, is more likely to account for the pulling of the testis into the scrotum.

The Function of the Testis.

It has long been known that the testis has a dual function Primarily it is a spermatogenetic organ, but it is also responsible for the development of the secondary sexual characteristics Hunter, in 1786, showed that the male sexual characters were independent of the production of spermatozoa, and that the development of the former was prevented by removal of the testes It is still undecided which element of the testis is responsible for the development of characteristic sexual changes The older, and perhaps more general opinion, is that the interstitial cells of Leydig produce an internal secretion which initiates the sexual changes at puberty It is significant that the onset of these changes is coincident with the reappearance of large numbers of cells of Leydig.

Recently it has been urged by Kenneth Walker that the spermatogenous cells produce the internal secretion He believes that the interstitial cells are merely trophic in their function, and furnish the tubular cells with nutritive material.

Pathology of Retained Testis.

In reviewing the older literature it was found that the retained testis was almost invariably described as abnormal in structure, and more or less useless to the individual so far as spermatogenesis was concerned Hunter stated emphatically that the retained gland was structurally imperfect, and he has received much influential support On the other hand, Curling, some 50 years after Hunter, concluded that the retained organ was not malformed originally, but was normal until puberty. Other workers, confining their studies to the retained testis in childhood, came to similar conclusions. Recently great interest has centred round the part played by the scrotum in spermatogenesis. It seems to have been proved conclusively by the researches of Crewe, Fukui, and Moore that the lower temperature of the scrotum is the essential factor for natural and complete spermatogenesis

Table I.—*Sizes of Scrotal and Retained Testes*

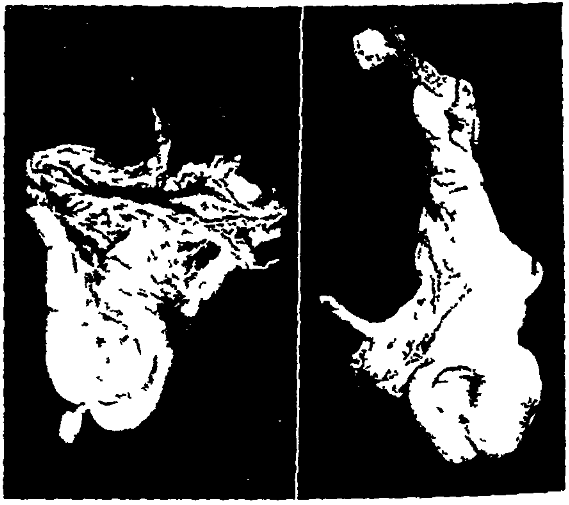
Scrotal.		Retained	
Age	L B T	Age	L B T
12 m	1 6 ×0 75 ×0 65	14 m	1 3 ×1·0 ×0 7
2 yrs	1 5 ×1 0 ×0 8	2½ yrs	1 1 ×0 75 ×0 6
3½ „	1 45 ×0 95 ×0 7	4 „	1 5 ×1 1 ×0 5
8½ „	1 7 ×1 0 ×1 0	6 „	1 8 ×1 2 ×0 8*
13 „	2 0 ×1 45 ×1 2	13 „	2 3 ×1 4 ×1 2
		13 „	3 2 ×2 4 ×1 7*
17 „	2 5 ×1 65 ×1 5	15 „	2 7 ×2 4 ×1 4*

L = Length Upper to lower pole
B = Breadth Anterior to posterior margins
T = Thickness Right to left surface
All measurements in centimetres
* Testes retained in abdomen m = months, yrs = years

The present investigation was undertaken in order to compare the structure of the retained and scrotal testes in children of the same age, and to see what changes occurred in the former organs as age increased Ten retained testes were obtained by operative procedure from children of varying ages and two from adults Each was a unilateral cryptorchid, and controls of similar age and of corresponding sides were procured from autopsies The dimensions were taken after fixation and are shown in the accompanying table (Table I) It will be seen that the size of the retained testis was very variable Those situated near the internal abdominal ring were usually smaller than the scrotal organ of the same age It is interesting to note that those glands arrested in the abdomen were invariably larger than the normal ones of that age, whilst those situated in the lower part of the inguinal canal were similar in size to the corresponding scrotal organ

It is proposed to describe briefly the gross and minute anatomy of the scrotal testis during childhood and adolescence, and afterwards to consider the retained organs and compare them with their controls. The scrotal testis at birth was of small size, but increased rapidly during the first few years Between the fifth and eighth years growth was apparently slower, but towards puberty advanced until adult dimensions were attained At first the epididymis and testis were of equal size in section, but later the growth of the former was slower, so that it was subsequently smaller than the testis

Fig. 1.



A, Testis retained in lower part of inguinal canal, aged 14 months B, Scrotal testis, aged 4 months In both cases the digital fossa is open and a vas aberrans is present

The relation of the epididymis to the testis was variable Usually the two structures were in apposition, but in a small percentage of cases they were separated by a digital fossa of variable width (Fig. 1 (B)) In nearly all those glands where the digital fossa remained open a stalked appendage was suspended from the lower pole of the testis This was the vas aberrans—a remnant of the Wolffian body, and in all cases was composed of vascular, cellular, fibrous tissue The parenchyma of the testis in early life consisted of small closed tubules isolated by delicate immature connective tissue Towards the end of the first year the tubules became closely packed, a minimum amount of fibrous tissue separating them. This condition prevailed except at two periods—during the second and third years, and between the ninth and eleventh years, when the tubules were again isolated by delicate stroma After this period the tubules increased greatly in size and were in close contact, being separated only by their basement membranes Except at the earliest ages the tubules all presented a central lumen, the tubular cells being arranged in rows within the surrounding fibrous basement membrane From fœtal life until the tenth year the tubules contained only two types of cells—undifferentiated cells and spermatogonia (Fig 2) The former were characterised by a pale, oval nucleus with irregularly arranged chromatin spots, surrounded by an ill-defined syncytial mass of vacuolated protowill be the tubular epithelium." Crew, working on the retained testes in horses, indicates that the further a testis lies from its normal position, the more abnormal are its appearance and histological structure. Crew, Fukui and Moore have recently urged that the presence of the testis in the scrotum is necessary for complete spermatogenesis. According to these workers the lower temperature of the scrotum is the essential factor. Keith, however, believes that the scrotal testis is relieved from the pressure in the abdomen exerted by the diaphragm.

2. At whatever position the testis is arrested, and at whatever pre-adolescent age it is examined, the essential elements of the gland—spermatogonia and undifferentiated cells—are. if not in all parts, certainly in many areas identical in position. structure, and relationship with those of the corresponding scrotal organ. This conclusion is comparable with that of Curling and his supporters, all of whom have described a healthy condition of the retained testis in childhood.

3 *The younger the age at which a retained testis is examined, the more are the normal appearances and characteristics found.* It may be stated conclusively that until puberty, the tubular cells retain their healthy pre-adolescent characters despite any reduction in the amount of parenchyma. After that time degenerative changes may occur which are more marked where a higher degree of retention prevails It may be added with confidence that a retained testis develops normally during the early part of postnatal life, but later. if it remains in its abnormal position, then and then only does it undergo retrogressive changes.

4 Certain changes are found to occur in the retained testis. They are recognisable as puberty approaches, and are most marked in the testes arrested in the abdomen or in the higher parts of the inguinal canal (1) The earliest change is the appearance of fibrous tissue which at first is of a primitive cellular nature. but later may become fibrosed. (2) There is an "apparent" disappearance of the tubules. due either to the failure of the gland to form new ones, or to the increase in the stroma causing a wider separation of those present (3) Later there is an "actual" disappearance of the tubules which may result from the advancing fibrosis (4) At puberty there is a persistence of the quiescent state of the nuclei of the spermatogonia

5 Throughout pre-adolescent life the undifferentiated tubular cells retain their vitality. and, as in the scrotal organ, undergo further specialisation into cells of Sertoli These are regarded as the nutritive elements of the spermatogenetic cells. It is remarkable to find that the cells of Sertoli are very resistant to the continuance of the malposition. and are typical even in adult life. Since the cells of Sertoli persist in retained testes it seems reasonable to suppose that they are trying to preserve the healthy condition of the germ cells. If, by the time puberty is reached. the testis is still misplaced, the cells of Sertoli seem to be incapable of preventing atrophic changes in the spermatogenous cells Should such a testis acquire its normal scrotal position prior to puberty. then the cells of Sertoli will be ready to continue their function of nourishing the germinal cells

6. The interstitial cells of Leydig are apparently not influenced by the abnormal situation of a retained testis As in scrotal glands they are in abeyance during early childhood and present and of typical appearance at puberty. and in the adult As far as could be judged they appeared to be in similar numbers in the scrotal and retained organs. The explanation of the apparent exaggeration so frequently described seems to be that they become more obvious because the tubules are less numerous or more widely separated.

7. In no cases of retained testis examined was there anything of an abnormal nature in the size or structure of the epididymis The only diversion was that more frequently in the retained testis the *epididymis* and testis were separated by a digital fossa of variable width but a similar condition was observed in some scrotal testes

THE FUNCTION OF THE RETAINED TESTIS

It is now generally agreed that double cryptorchidism in both man and animals is associated with aspermatogenesis, but the elaboration of the internal secretion responsible for the production of the secondary sexual characters is complete Great interest has centred round this aspect of the subject, and much valuable research work has been carried out. Hunter considered that the absence of spermatogenesis was due to the imperfect development of the retained testis and Bland-Sutton supports this view. Curling concluded that the testis was normal in form and structure until puberty, when further evolution ceased. Murdoch was of the opinion that the retained testis acquired its mature structure at puberty, but later underwent atrophy owing to its faulty position.

After careful histological examination of the retained testis and comparison with the scrotal gland. it is suggested that the abnormal changes are secondary. It is surmised that the retained testis develops normally during early postnatal life. but later if it does not reach the scrotum, it undergoes retrogressive changes

In some animals the testes are normally situated within the abdomen and only pass into the scrotum during the breeding season. when the process of spermatogenesis is active After this period the glands are withdrawn into the abdomen by the cremaster muscle, shrink to half their size, and are said to resemble the retained testis in man. In these mammals the testes are only spermatic when in the scrotum, the lowermost point of their descent In man the glands have come to reside permanently in the scrotum, and. as in those mammals where intermittent descent takes place, only acquire their full development and function when they reach the terminal point of their destined course.

It becomes evident. then that the functional activity of the testis depends upon its anatomical situation Since the position in the scrotum is essential. it is justifiable to surmise that retained organs may complete their development if placed by operative procedure into the scrotum before they are seriously compromised.

TREATMENT.

Owing to the frequently unsatisfactory results following surgical intervention in these cases, surgeons sometimes postpone operation in the hope that descent of the testis will occur naturally Spontaneous descent however. is not common after the first three years of life and this form of treatment is to be discouraged In view of the complications associated with retention of the testis, the treatment becomes a matter of considerable importance The testis in the inguinal canal is exposed to pressure from the contraction of the abdominal muscles. causing pain, inflammation, and subsequent fibrosis. Hernia is usually associated with retained testis and the risks of torsion and malignant disease are not to be ignored. It appears only logical to preserve an organ which is of such great importance to the human economy. and every effort should be made to place the testis in surroundings favourable for its protection and maturation Whilst freely admitting that it is as yet uncertain whether a testis which has been transplanted into the scrotum will develop and function normally. it is believed that if this can be done in early life without injury to the structures concerned there is a reasonable prospect that the organ will become efficient Even if the dual rôle of the testis is not acquired, the gland should never be sacrificed owing to its power of producing the internal secretion on which depends the development of the male characters Furthermore, its presence in the scrotum will be a source of satisfaction to the sensitive individual. whilst it is always desirable to restore conditions to normal if it be possible without undue risk.

Apparently the retained testis is more liable than the normally placed organ to undergo malignant degeneration In a series of 45 cases of malignant accompanying hernia The retained testis at 14 months (Fig 3) was, histologically, practically identical with the scrotal organs from children aged 10, 11, and 12 months The surrounding tunica albuginea was of similar width, the tubules were all closely packed and of equal size, and contained healthy undifferentiated cells and spermatogonia The interstitial tissue was of a fibrous nature, and the basement membranes fully formed Interstitial cells of Leydig were in abeyance as in scrotal glands of this period

One histological feature alone distinguished this retained gland from corresponding scrotal organs, and that was a slight thickening of the fibrous interstitial tissue in the centre of the organ In consequence it was assumed, by careful comparison between this retained testis and the normal ones, that the parenchyma of the former was healthy, but its development was slightly retarded, in other words, the gland, during 14 months, had attained the condition of a scrotal organ of under one year.

The retained testis at the thirteenth year was equal in size to normal testes of this age The tubules were numerous and fairly closely packed, and similar in size to those of a completely descended testis at the twelfth year The basement membranes were fibrous, but cellular stroma occupied the small intertubular intervals Differentiation of the undifferentiated cells was proceeding as in normal testes, and characteristic cells of Sertoli were recognisable. The spermatogonia (Fig 4), however, although numerous, were still in the resting condition as far as spermatogenesis was concerned It is concluded therefore that this testis was healthy, but in a pre-adolescent condition, its development again having been retarded. It must be added, however, that a similar condition was found in a scrotal testis of 13 years where the tubules were small, and contained simple, resting spermatogonia and specialised undifferentiated cells The cells of Leydig were similar in appearance and numbers in both testes

It is interesting to record that the testis arrested in the external abdominal ring in a man of 60 years contained some degenerated tubules and many active ones The latter showed complete spermatogenesis, even to the formation of spermatozoa

Two testes from children aged 4½ years, and one from a child of 2½ years, retained in the higher parts of the inguinal canal, were smaller than the corresponding scrotal organs In both cases the tubules were separated, cellular stroma occupying the intervening spaces At the earlier age they were irregularly scattered, a group of tubules alternating with a mass of stroma ; at the later age they were more evenly distributed The tubular cells were of two types, undifferentiated cells and spermatogonia On the whole, the latter were less frequent than in the fully descended organs of this period Cells of Leydig were in abeyance as in the normal testes

In comparison, then, with scrotal glands of this age there appeared again some retardation of development, with possibly actual reduction of the parenchyma The glandular elements present, however, were in a healthy condition In these cases it is to be observed that a more marked arrest of development was associated with a higher degree of retention Two testes arrested at the internal abdominal ring in children aged 4 and 5 years were examined. At the former age the gland was characterised by a progressive fibrosis which apparently had commenced posteriorly at the mediastinum testis and spread towards the anterior margin, where cellular stroma was still recognisable At five years the intertubular tissue was of a cellular nature In both cases the tubules were smaller than in the corresponding scrotal glands, and they were isolated and evenly scattered They contained simple, undifferentiated cells, and two or more spermatogonia Compared with scrotal testes at the fifth year it appeared that in these two retained organs there was an appreciable arrest of development, the number of tubules being smaller than in the healthy organ, and their isolation in marked contrast with the closely packed arrangement in the fully descended gland But again the tubular elements, though collectively reduced in amount, were of characteristic appearance and structure

In considering the glands arrested in the abdomen, from children aged 6, 13, and 15 years, the large size of these organs was very striking On examination this was found to be accounted for by a predominance of fibrous tissue, and not by an overabundance of parenchyma In each case the testis and epididymis were separated by an extraordinary wide digital fossa, and in those of 6 and 13 years a large, stalked vas aberrans was present The tubules in the glands of 6 and 15 years were evenly distributed, but isolated by delicate cellular connective tissue. At the thirteenth year the tubules were considerably reduced in size and number, and were confined to the region adjacent to the tunica albuginea (Fig 5) The greatest part of this organ consisted of dense fibrous tissue The contents of the tubes in the gland at 6 years appeared to be in a healthy condition. Typical undifferentiated cells and spermatogonia were present, although the latter were far less frequent than in the corresponding scrotal organ At the thirteenth year the parenchyma was extensively reduced. Only a few spermatogonia were recognised, specialised undifferentiated cells filling the tubes In the retained testis at 15 years the tubular cells were in many cases degenerated, but many typical cells of Sertoli were seen, and an occasional spermatogonium could be distinguished Cells of Leydig were not observed in the testis at the sixth year, but in the others they were characteristic and occupied only the intertubular intervals It appeared, therefore, that abdominal retained testes were subjected to an invasion of fibrous tissue, accompanied by different degrees of degeneration and disappearance of the tubules. It is impossible to say whether the fibrosis was a primary change causing retrogression of the tubular elements or whether it was secondary, replacing the already compromised parenchyma

It is interesting to include in this series a small body removed along with a hernial sac from the inguinal canal of a human hermaphrodite of 38 years It consisted of small tubules isolated by vascular, fibrous tissue and masses of cells of Leydig In the half dozen sections available, the tubular cells were seen to be mostly typical cells of Sertoli, but two spermatogonia were recognised, one characteristic of the resting condition, and the other presenting a state of nuclear activity.

After a careful comparison of the retained testis and scrotal organ in children at different ages and in different situations, it seems justifiable to draw the following conclusions —

1 *The further the pre-adolescent testis has descended in its normal route the more closely does it correspond to the scrotal gland of the same age* It has been shown that two testes arrested in the lower part of the inguinal canal in children aged 14 months and 13 years were similar to scrotal glands of the same age, others retained in the upper part of the canal showed a reduction in the amount of glandular parenchyma, but a healthy condition of the existing essential elements Glands arrested in the abdomen were affected by different degrees of fibrosis and a greater reduction in the germinal elements, but amongst those persisting, healthy forms could be distinguished A testis found in the external abdominal ring in a man of 60 years showed complete spermatogenesis in parts Hunter believed that an abdominal retained testis was more imperfect than one late in getting into the scrotum ; whilst Bland-Sutton is of the opinion that a healthy testis is never found in the inguinal canal

Recently Moore has carried out experimental elevation of the testes in animals, and later has replaced these glands into the scrotum He finds that “ the more nearly the testis so treated returns to its normal scrotal position, the more nearly normal

The vas deferens usually offers no difficulty in transplanting the gland, and the spermatic cord can generally be sufficiently lengthened by dividing the fascial and muscular bands, which are the chief obstacles in bringing down the testis

In cases where the blood-vessels of the cord appeared too short, Bevan of Chicago, in 1898 proposed that additional length could be secured by ligaturing and dividing one or more of the spermatic vessels He considered that the vessels to the vas were sufficient to nourish the testis This method has the disadvantage that it may be followed by atrophy of the testis and is not to be recommended except as a last resort.

Technique of the Operation.

The chief stages in the operation that we have adopted are carried out as follows The skin incision is made just above Poupart's ligament and exposes the whole length of the inguinal canal. The external oblique aponeurosis is divided and the spermatic cord and hernial sac then identified. The sac is separated from the cord near the internal ring, transfixed, ligatured and cut across when the stump will slide out of view under the fibres of the internal oblique muscle. This completes the first stage of the operation The fundus of the sac is now drawn up and freed from its attachment to the bottom of the scrotum. The testis is thus mobilised and can be drawn out of the wound. It is handled as little as possible during this and subsequent manœuvres The constituents of the cord are next separated with the utmost care. and all fascial and muscular bands stripped up to the internal ring the cord being put on the stretch. This is a somewhat tedious performance, but is of the utmost importance The testis finally is held only by the vas and spermatic vessels, and the latter are traced by the finger into the retroperitoneal tissue towards their origin from the aorta and separated from surrounding structures Similarly, the vas is followed down into the pelvis and further mobilised The cord having been sufficiently lengthened by these manipulations to enable the testis to be placed in the scrotum without tension, the organ is laid in its new position after a bed has been prepared there for it with the finger A mattress suture previously passed through the remains of the gubernaculum and tunica vaginalis below the testis is tied over rubber tubing outside the scrotum This anchors the testis into its pouch. There should be no tension on this suture which merely steadies the testis for a time in its new position. The wound is then closed and the patient remains in bed for three weeks.

The operation is one which requires considerable care and patience in its performance, owing to the delicacy of the structures concerned If sufficient length of the cord can be obtained after the testis has been freed from the hernial sac and all the fascial bands divided the final result is generally satisfactory. Handling of the testis must be avoided if possible to prevent injury and postoperative swelling and perhaps subsequent atrophy. In bilateral cases an interval of several months is allowed to elapse so that the result of the first operation can be ascertained before the second is undertaken If the first operation prove successful, the second testis is brought down; if it fail, it may be wiser to leave the testis alone

When the testis can be transplanted into the scrotum with its blood-supply intact and not under tension the organ will remain there and develop satisfactorily An operation is considered to be an anatomical success when the testis maintains its position in the scrotum and hangs freely without adhesions around it The organ must be of normal consistence and continue to grow as the age of the child increases The actual height at which the testis lies in the scrotum is of no great importance, for normally one organ lies at a higher level than the other If the testis feels hard and small, fibrosis has taken place and the operation must be regarded as a failure.

OPERATIVE RESULTS.

During the past five years 50 cases of inguinal retention of the testis have been treated by placing the testis in the scrotum. In 38 cases, one side only was concerned, whilst in 6 cases both sides were submitted to operation. The ages of the children varied from 3 to 14 years, the average being 7 years All these cases have been carefully followed up, and the time that has elapsed since operation was performed varies from 1 to 5 years. The results are shown in Table II. Thirty-six cases gave good anatomical results, 14 were failures Two cases occurred in twins and in both brothers a retained testis, accompanied by a hernial sac, was found on the right side.

TABLE II.—*Operative Statistics*

I *Preoperative Data*

Number of patients	44
Testes operated upon	50
Involving right side	21
Involving left side	17
Bilateral cases	6
Age at operation	3–14 years.
Average	7 "
Position of retained testis—inguinal retention	

II. *Postoperative Data.*

End-results in 50 cases of retained testis	
A. *Successful*: 36 cases.	
Testis free in scrotum. Normal size and consistency	72 %
B. *Failures*: 14 cases	
Testis retracted and/or atrophic	28 %
C *Bilateral cases*	
(1) Both testes in scrotum in 3 cases.	
(2) One testis in scrotum in 3 cases.	
D *Hernia present in 46 cases*	92 %
Spermatic vessels divided in 4 cases	
Atrophy of testes in all 4 cases	100 %
Mortality	Nil

The operation as described has proved satisfactory (Figs 6 and 7) and there has been no mortality in the series

CONCLUSIONS

In conclusion, it appears justifiable to advocate the transplantation of the inguinal retained testis into the scrotum during the first years of life.

As a result of a careful histological investigation the retained testis has been found to be very similar to the scrotal organ in early childhood

Good results after operative treatment are not exceptional, and there is a reasonable prospect that the transplanted testis will acquire the spermatogenetic function at puberty, provided the organ be placed in the scrotum before morbid changes have occurred The presence of a living testis in the scrotum in a considerable percentage of cases justifies the performance of the operation. It must be added, however, that as yet there has been no mortality in the series quoted and consequently no histological confirmation of spermatogenesis in the transplanted organ

We wish to express our sincere thanks to Prof J. S. B. Stopford in whose department much of the work was carried out, for his help, advice and kindly criticism We also wish to thank Sister M. McMurtrey for her assistance in collecting the cases after operation, Mr. A Teesdale and Mr. H Gooding for the excellent photographs of the patients and specimens.

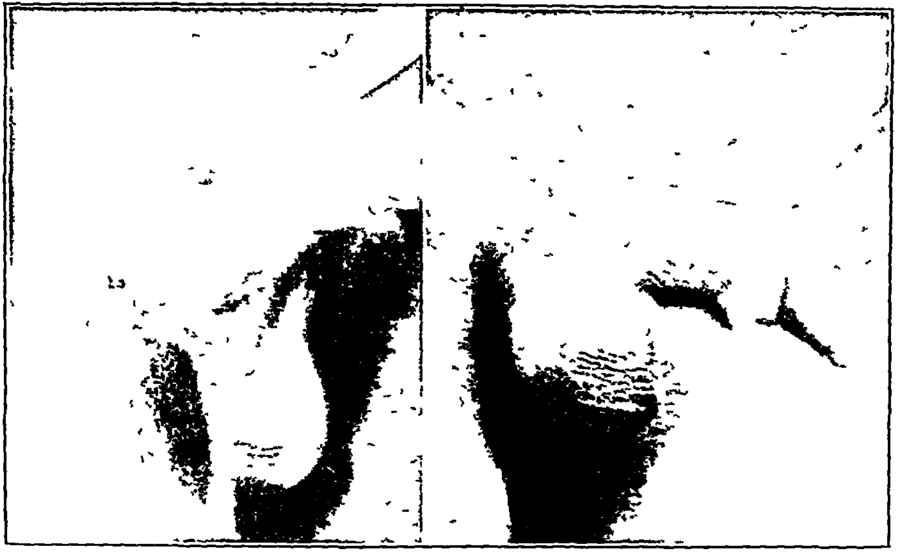
testicular tumours collected from the Manchester Hospitals, over a period of 15 years, seven cases occurred in the retained testis Dew, in reviewing the published figures, comes to the conclusion that malignancy is relatively more frequent in the abnormally placed testis, though this tendency has probably been exaggerated This complication is rare in childhood, and operation in early life should therefore help to lessen its occurrence in later years

The adoption of traction and gentle massage of the testis in an attempt to encourage its spontaneous descent during the first years of life will not endanger its future development The wearing of a truss must be strongly discouraged, for whilst it may control the accompanying hernia, the pressure on the testis leads to attacks of inflammation and subsequent fibrosis of the gland Hunter realised this danger when he wrote, "the surgeon who is employed should be very attentive that no inconvenience is produced by the truss"

FIG 6 FIG 7.



CASE 1 —Right inguinal retained testis and hernia

Before operation After operation

In several cases where testicular gland or thyroid extract has been employed no beneficial results have followed If the testis does not reach the scrotum by the third year of life, the chances of it coming down unaided are remote

If, then, the testis has not reached the scrotum by the age of three years, that is the time of election for operative treatment to be carried out After this age the gland is subjected to retrogressive changes in the parenchyma and sometimes a progressive fibrosis If it be placed in the scrotum at this early age it is believed that the degenerative changes will be prevented, normal development may occur, and the power of procreation be preserved The anatomical structures are sufficiently well developed at the third year to warrant easy recognition and so prevent injury. Little is to be gained by delaying operation after this period, for as the age of the individual increases, the chances of success following operation decrease, owing to the morbid changes becoming more pronounced

Indications for Operation—In deciding which cases are suitable for operation it will be remembered that the retained testis may be found in three positions (1) abdominal or iliac, where it lies proximal to the internal abdominal ring and cannot be detected on palpation; (2) inguinal, where it is arrested within the inguinal canal; and (3) high scrotal, where the testis has passed just outside the external abdominal ring.

Cases of iliac retention, which are the least common type, are not, in our opinion, suitable for transplantation to the scrotum as a general rule The vessels are so short that it is only possible to bring these testes down after their division, and this often results in atrophy of the organ The vas itself, after repeated observations, does not appear to be correspondingly shortened When unilateral, these cases should be left alone unless complications require interference If both sides are affected, it is justifiable to try to bring one testis down into the scrotum If the operation succeed it affords the patient a chance of fertility, if it fail, and the organ undergoes fibrosis, the remaining testis will furnish the internal secretion necessary for the individual's future development

In the high scrotal group, where the testis has escaped just outside the external abdominal ring, operation is rarely necessary Such a testis has been seen to develop normally and should be left untouched unless an accompanying hernia requires treatment Testes in this situation may undergo spontaneous descent into the scrotum as the child grows and a hernial sac is often absent It may be advisable to keep such cases under observation until descent is complete The inguinal group comprises the largest number of cases, and all should receive operative treatment—namely, *transplantation of the testis into the scrotum.*

Briefly, all cases where the organ is palpable in the inguinal canal should be submitted to operative treatment

OPERATIVE TREATMENT.

In the operative treatment of this condition three different procedures are available —

(1) The testis may be excised Removal of the testis in a child is to be strongly condemned unless some serious complication intervenes The objection to removing the organ is that even though it may be of little spermatic value, the presence of the internal secretion may justify its retention

(2) *The testis may be replaced in the abdomen* This procedure is advocated by Pannett in view of the large number of failures following scrotal transplantation This operation offers little hope of the development of the spermatogenetic function and exposes the testis to the risk of malignant degeneration It is said, however, that the danger of malignant disease is less when the testis lies in the abdomen than in the inguinal canal. Abdominal replacement should only be carried out when the testis cannot be brought into the scrotum

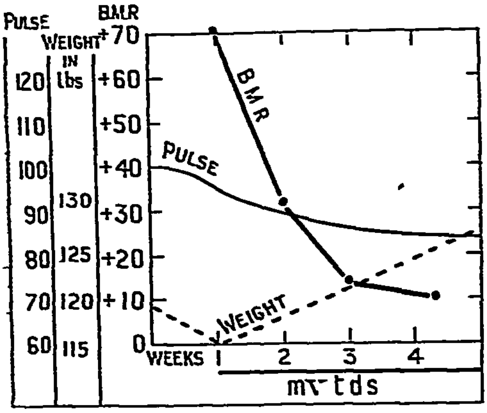
(3) The testis may be transplanted into the scrotum This is the ideal operation and places the organ in its natural position, and gives it a chance of developing its full functions

The cases in this series have all been treated by bringing the retained testis down into the scrotum and placing it in a bed that has been prepared to receive it

If the operation is to be successful the blood-supply of the testis must not be interfered with, as this will endanger its vitality and subsequent growth Further, the testis must be placed in the scrotum without tension, otherwise retraction will certainly take place

In estimating the basal metabolic rate the samples of air for analysis were collected by the Douglas bag method This was done in a large general ward, but although screens were used to cut off outside excitements as far as possible, the conditions were not ideal. The patients had no food for 12 hours before the test.

FIG 2.



CASE 2 —Severe exophthalmic goitre Female aged 31.

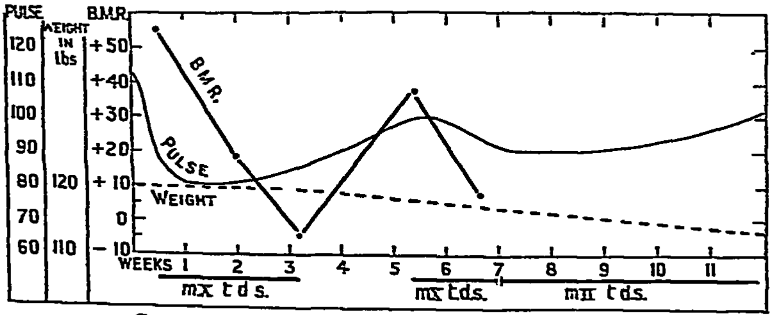
Dosage and Duration of Treatment

Five or ten minims of Lugol's solution (an aqueous solution of 5 per cent iodine and 10 per cent potassium iodide) were given three times a day during treatment. The larger dose was given at the beginning of treatment, but never for longer than six weeks, and usually for a shorter time. The duration of treatment and dosage is given in the table opposite. In most cases 5 minims three times a day seemed a safe and efficient dose to be continued without remission for several months, and this was given also to out-patients with benefit and no ill-effects

Results of Treatment

1. *Effect on Symptoms and Physical Signs*—During the first few weeks the subjective symptoms of palpitation, nervousness, heat, and gastro-intestinal discomfort were greatly diminished or disappeared entirely. The pulse became slower, the tremor less, and the patients were cooler, more composed, and slept better The maximum improvement was reached after from ten days to six weeks continuous iodine After a few weeks the exophthalmos was usually less and the gain in weight had begun If iodine was continued after this period the response varied in different patients Some relapsed slowly but the disease did not reach its former severity while they continued to take iodine, others remained stationary in a greatly improved condition Three cases showed no tendency to relapse after continuous treatment for five months, but these all retained signs of mild hyperthyroidism although the basal metabolism remained normal in two of them

FIG 3.



CASE 7 —Severe exophthalmic goitre. Female aged 23

2 *Effect on Body-weight*—Most cases showed a steady increase in weight after the first week. In this series 14 out of 19 gained weight while taking iodine Case 12 was kept at rest in bed for four weeks without treatment and lost 7 pounds She was then given iodine for 12 weeks and steadily gained 17 pounds The gain in weight did not always synchronise with a fall in basal metabolic rate In Case 12, again, while iodine was given for 12 days the weight increased slightly and the basal metabolic rate fell from +70 3 per cent. to — 1 per cent. During the next two months the basal metabolic rate rose from — 1 per cent to + 60 per cent., and there was a gain in weight of 13 pounds. In Case 1 the basal metabolic rate fell from — 65 per cent to + 5 per cent in 11 days and the weight increased by 2 pounds Iodine was continued for the next three months and during this time the basal metabolic rate rose again to + 46 per cent, and the weight increased 24 pounds In most instances, however, a fall in basal metabolic rate is accompanied by a rise in weight

TABLE I.—*Showing the Effect of Lugol's Iodine on the Basal Metabolic Rate in Cases of Exophthalmic Goitre.*

B M.R. = Basal metabolic rate Op = Operation.

CASE 4—Aged 6. B M.R. not estimated, but great clinical improvement on ♏i.—♏ii. t d.s for ten weeks.

The five cases who lost weight did not do so well in other ways as those who gained. Three relapsed quickly after moderate initial improvement, one failed to improve at all, and the fifth improved clinically for a fortnight, and then developed acute mental symptoms It appears to be a useful working rule that patients who fail to gain weight without apparent additional cause during the first few weeks of treatment will not react well in other ways and no very sustained improvement may be expected even if iodine is continued

3 *Effect on basal metabolic rate* is shown in Table I

THE USE OF LUGOL'S IODINE IN EXOPHTHALMIC GOITRE.

BY L B COLE, M D. CAMB, M R C.P LOND,
RESIDENT ASSISTANT PHYSICIAN TO ST THOMAS'S HOSPITAL.

A STUDY of the effect of iodine in exophthalmic goitre is of interest from two points of view In the first place, it is important for the clinician to know its exact value in treatment and to what extent different types of the disease will respond. In the second, since iodine does cause a change in the metabolism, it is possible that a study of this effect may lead to a clearer understanding of exophthalmic goitre and throw light on its causation.

Historical Summary

The use of iodine by the mouth in hyperthyroidism was for many years taboo This was largely the result of Kocher's [1] observations on the treatment of simple goitre with iodine He showed that the firmer and more nodular types thus treated quickly developed hyperthyroidism and he condemned its use both in adenomata with hyperthyroidism and in true Graves's disease This condemnation persisted until a few years ago and still lingers

Marine and Lenhart,[2] however, and later Neisser [3] treated cases of Graves's disease with small doses of potassium iodide with very encouraging results, and in 1921 Loewi and Zondek[4] confirmed these observations Further, in three cases they estimated the oxygen consumption after iodine treatment and found that it was reduced to normal

Iodine then began to be used extensively in America as a preparation for partial thyroidectomy in exophthalmic goitre Plummer and Boothby [5 6] gave it in the form of Lugol's solution to 600 cases Ten minims were given daily for a few days to a fortnight before operation and in very severe cases the dose was increased In 40 careful observations of the clinical condition and basal metabolism were recorded The results were highly satisfactory, for they found that two-thirds of those treated were greatly benefited In these the nervous and gastro-intestinal symptoms disappeared in a few days, the pulse was slowed, the signs grew less, and the basal metabolic rate was reduced to normal The most striking and definite results were obtained in the most severe cases In the remaining third the results were less good, but very few failed to improve They emphasised the value of iodine before operation in reducing the surgical mortality and commented on the fact that the only surgical death from exophthalmic goitre that occurred in seven consecutive months at the Mayo Clinic was the only case to which lugol had not been given at the time of operation They considered that iodine should with few exceptions be used only as a temporary measure to bring the patient into a safe condition for surgical treatment

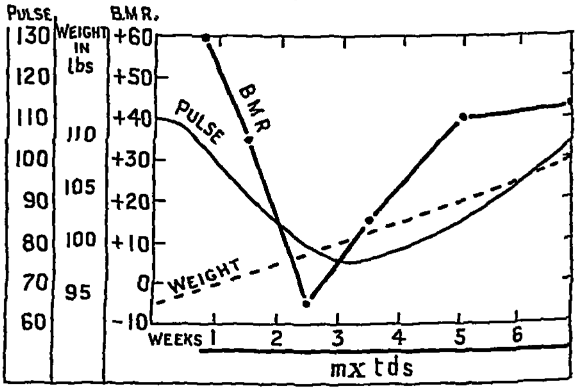
Sturgis and Greene [7] studied two series of cases, to one of which lugol was given before operation They showed that when the basal metabolism was reduced to normal with lugol before operation the loss of weight after operation was slight or there was an actual gain The untreated cases all lost a great deal of weight

Reinhoff [8] examined the histological changes in the thyroid gland after lugol treatment, and showed that the clinical improvement and lowered rate of metabolism are directly associated with the change from the typical histological picture of exophthalmic goitre to a resting colloid state He concluded that an artificial remission of the disease was produced by iodine This, he thought, is probably what also takes place during a normal remission of the disease and possibly explains the confusing histological appearances that have been described

In England iodine has only been used in exophthalmic goitre during the last few years At a discussion on the treatment of exophthalmic goitre in 1922 iodine was vetoed as dangerous for those who showed any signs of hyperthyroidism Only one speaker, Prof David Drummond,[9] said that he was accustomed to give potassium iodide in small doses to these patients, often with considerable benefit

Dr R Fraser [10] used iodine at St Bartholomew's Hospital His results agreed with those of workers in America as to its striking initial effect He found that the improvement did not as a rule persist, and cessation of iodine was followed by immediate relapse The iodine was given in the form of a 10 per cent solution in alcohol and the optimum dosage at the onset of treatment was found to be 15 minims a day, though this was reduced to 3–6 minims daily as soon as the initial improvement had taken place. Too large a dosage made the patient worse instead of better

FIG. 1



CASE 1 —Severe exophthalmic goitre Female aged 21

S J Cowell and E Mellanby observed the effect of iodine in the form of potassium iodide on eight cases of exophthalmic goitre, and their observations agreed with those of previous workers. They found no grounds for regarding iodine treatment as curative, but considered it a valuable adjunct to previous medical and surgical treatment, and suggested that the optimum dosage might be found to be in the region of one-tenth of a grain of potassium iodide daily for the majority of cases

The Present Investigation

In the series to be described, Lugol's iodine was given to 19 cases of hyperthyroidism and its effect on the clinical condition was observed In 17 cases the basal metabolism was watched concurrently, and in five cases observations were made on the sugar tolerance In all of them the condition was apparently true exophthalmic goitre, but it is possible that the three who reacted badly may have been atypical examples of toxic adenomata

All the patients were kept in bed during the first few weeks of treatment and were given the ordinary hospital diet equivalent to about 2200 calories Later treatment was continued while they attended as out-patients at intervals of a week or a fortnight.

glucose This is most likely due to an effect on the storage mechanism of the liver. Confirmation of this is found in the effect of thyroid feeding in depleting the liver of glycogen[13] and by the fact that thyroid feeding in the normal individual may lead to the development of a similar type of sugar curve to that found in exophthalmic goitre

If this impaired sugar tolerance were the result of altered thyroid secretion it seemed possible that the effect on the basal metabolic rate might be accompanied by an improvement in sugar tolerance It is suspected that both thyroxin and adrenalin are able to inhibit the storage of glycogen by the liver and to cause the breakdown of previously formed glycogen into sugar Possibly iodine, by altering the secretion of the thyroid gland may indirectly prevent its inhibitory effect on the storage mechanism and thus make storage more efficient and increase the sugar tolerance.

In four cases of this series the sugar tolerance was estimated by MacLean s method before and after treatment with Lugol's solution. The basal metabolism was also estimated before each test In the fifth the sugar tolerance and basal metabolism were estimated after nine months' continuous iodine treatment The results in Table II show a marked improvement in one case a slight change in two, and no change in one The sugar tolerance in the fifth was still greatly impaired after nine months' iodine. although the basal metabolism was normal Iodine appears to have slight influence on the impaired sugar tolerance in hyperthyroidism -It is possible that it may cause a transient initial improvement which coincides with the lowering of the basal metabolic rate

Conclusions

Lugol's iodine given to cases of true exophthalmic goitre has the following effects —

The symptoms and signs are lessened. A point of maximum improvement is reached after from two to six weeks' continuous treatment Most cases then relapse slowly even though iodine is continued. Clinically a low grade hyperthyroidism persists

The *weight* is increased The *basal metabolic rate* is reduced to normal limits after from one to six weeks In most cases it then rises slowly again even if iodine is continued. Cessation of iodine is followed by an immediate rise The *sugar tolerance* appears to be slightly improved in some cases.

Five to ten minims of Lugol's iodine three times a day is a safe and efficient dose in most cases for the first few weeks' treatment and 5 minims may be continued safely and with benefit to some patients for six months An increase of symptoms, however during treatment is an indication for a smaller dose An abnormally firm thyroid gland. exceptionally severe nervous symptoms or loss of weight during the first few weeks of treatment are warnings that Lugol s iodine may be dangerous

In conclusion I should like to thank Dr A. E. Russell, Dr. E F. Buzzard Prof H MacLean Dr. M A. Cassidy and Dr R. C Jewesbury for permission to investigate cases in their wards at St Thomas's Hospital

THE GROWTH OF TUMOUR IN TISSUES EXPOSED TO X RAYS AND RADIUM *

BY S RUSS, D Sc.

AND

G M SCOTT.

(*From the Cancer Research Laboratories, The Middlesex Hospital*)

PREVIOUS experiments have shown that rats which have been exposed to repeated small doses of X rays and afterwards inoculated with Jensen s rat sarcoma (J R S) do not grow the tumour quite so quickly as do normal rats[1] Murphy[2] found that after purely local irradiation of the skin of mice *intra*-cutaneous inoculation of tumour rarely grew, but in the case of *sub*-cutaneous inoculation there was very little difference between the growth in the treated mice and the controls As these observations have some bearing on the therapeutic uses of X rays and radium, more experiments on these lines have been carried out; and from the data in the following paper it seems pretty clearly indicated that sarcoma of the rat, implanted subcutaneously. does not grow at the normal rate in a region which has been given a suitable dose of radiation

FIG 1

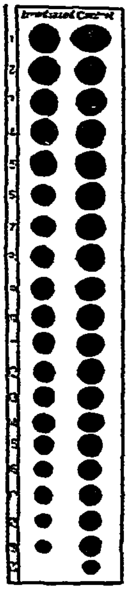

FIG 3

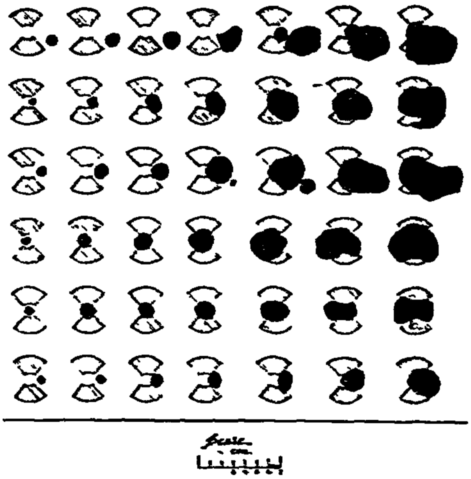

FIG 1 —Left column = irradiated animals Right column = normal animals

FIG 3 —Preferential growth of tumour into non-irradiated tissue.

Preliminary Experiments

Young rats were inoculated on the flank with small pieces of J R S.; three or four days later the graft was covered with a lead disc 1 mm. thick and 9 mm diameter, and the surrounding tissue exposed

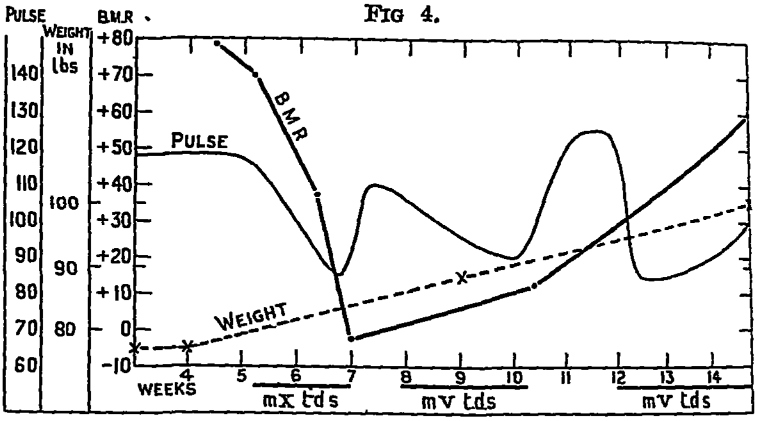
* A paper read at the Section of Electro-therapeutics, Royal Society of Medicine, on April 8th

[1] Russ Chambers, and Scott Proc Roy Soc, B vol xcvii, 1921 [2] Murphy J B Jour Exp Med., 1921 et seq

The initial lowering of the basal metabolic rate to normal was very constant and occurred in 13 out of the 14 cases in which it was estimated Two to three weeks' treatment was the average time required for this When iodine was continued after this point of maximum improvement the basal metabolic rate rose again in most In two cases only, after six and nine months' treatment respectively, was it still below normal Lugol's solution was also used successfully in one patient whose symptoms and signs, though relieved by partial thyroidectomy, were not cured Six months after operation the basal metabolic rate was still + 39 per cent Iodine treatment was then given for three months and at the end of this time the basal metabolic rate was + 3 per cent, and she appeared to be cured

Fig 4.

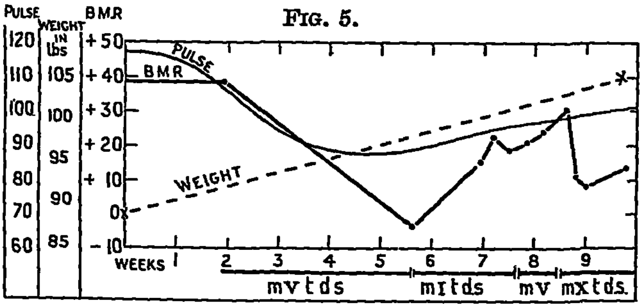


Case 12 —Severe exophthalmic goitre Female aged 26

Intolerance

No cases of iodism were noticed Increased nervous symptoms may have been due to iodine in three patients The first was a woman with moderately severe hyperthyroidism which had supervened on an adenoma of many years' standing Thirty minims of Lugol's solution in two days caused a marked increase in nervous symptoms These abated when treatment was stopped

Fig. 5.



Case 13 —Severe exophthalmic goitre Female aged 32

The second (Case 6) appeared to be a moderately severe example of true exophthalmic goitre Nervous symptoms were unusually predominant and the thyroid was exceptionally firm and nodular. Only slight exophthalmos was present After doing well for a fortnight (see Table I.) he became maniacal and had to be controlled with morphia and hyoscine

Case 19 was a severe example of true exophthalmic goitre with a large, firm thyroid and moderate exophthalmos Ten minims of Lugol's solution were given three times a day for three weeks and during this time the thyroid became extremely firm and the clinical signs and symptoms improved only slightly She then became excitable and developed illusions of persecution. Iodine was stopped and sedatives controlled the condition which slowly subsided

The presence of an abnormally firm or nodular thyroid and exceptionally severe nervous symptoms appear to be contra-indications to the giving of iodine Failure to gain weight while taking it is another indication for caution Failure to improve is an indication for reducing the dose

Effect of Iodine on Sugar Tolerance

The profound effect of iodine on the basal metabolic rate in exophthalmic goitre suggested that it might also influence the decreased sugar tolerance in that disease

Table II —*Showing Sugar Tolerance Before and After Treatment with Lugol's Iodine.*

It has been shown by Sangar and Hun [12] that in conditions of hyperthyroidism sugar, when offered to the tissues, is burned with great avidity and the increased utilisation of carbohydrate after carbohydrate ingestion along with the maintained high blood-sugar curve point to an inability to store

OUTBREAK OF ENTERITIS NEAR GLASGOW.

A BACTERIOLOGICAL ACCOUNT

BY W R WISEMAN, M B, B Sc, F R F P S GLASG

(From the Public Health Laboratory, Corporation of Glasgow)

IN October, 1926, throughout an area bordering on the Clyde, a large number of persons (over 80) were seized with enteritis, the cases occurring over a period of some weeks The duration of illness of the patients who came under bacteriological notice was short—four to seven days—with the exception of one who suffered three relapses, and one, aged 70, who was ill for three weeks Adults as well as children were involved It was suggested that the milk-supply should be scrutinised, and accordingly the first six specimens of fæces submitted for bacteriological examination comprised three from patients in the village and three from persons on the farm supplying the area with milk Five of these six specimens yielded the organism which was the cause of the trouble The various organisms will be referred to here as the bacilli of Lang, Arneil, and Stewart (the villagers), and of A.B 2 and A.B 3 (the wife and daughter respectively of the farmer A.B) A B delivered the milk personally, but his stools failed to yield the organism on two examinations It is interesting and of some importance that A B 2 had never exhibited any symptoms, though the organism (in small number) was got on the first examination A B 3 had had diarrhœa at the beginning of October, and her organism was found on the first examination, 13 days after the onset Besides those five organisms three samples of blood sera fell to be examined—viz, from A B, Lang, and another patient Lyle

During the first few days of incubation the reactions of all the five organisms in the biochemical tests were identical with those of the dysentery bacillus of Flexner, but after the first week or so these reactions altered so as to become the same as those characterising the organisms of Sonne's Group III of dysentery bacilli [1] It is not proposed here to describe these changes Attention having been directed to these two groups during the investigation, it follows that the serological work may best be described under three heads (1) Relations with Flexner Y bacilli and sera (2) Results of the interaction between the isolated organisms and the patients' sera (3) Relations with Sonne III immune sera

It must be stated at this point that on the plate culture from Stewart one or two rough dry colonies appeared among the predominating smooth, moist ones These were the same organism Stewart "rough" was agglutinable throughout in a manner that contrasted strongly with Stewart "smooth" and with the other members of the series As it was agglutinable even by a Flexner V serum (1/100 in 24 hours, with no reaction in 1/25 in five hours) it is not necessary for the purposes of our conclusions to take the figures associated with it at their actual face value On the other hand, rough variants (if this be one) of the Sonne III type of organism may have it as an inherent property to be somewhat more sensitive to specific agglutination than the type colony, and indeed the writer has noted this phenomenon in relation to other species of organisms Time was not given to work out this point Rough variants have not hitherto been noted in connexion with the Sonne III group.

1 (*a*) Artificial agglutinating sera for *B dys* Flexner V, X, Z, and Y (titres 200) failed to agglutinate the bacillus of Lang and of A B 2 in dilution 1/25 in 24 hours at 52° C As already noted, *B* "Stewart" (rough) reacted in dilution 1/100 of a Flexner V serum in 24 hours (*b*) Lang's serum and Lyle's serum (both taken at a favourable period) were both negative to *B. dys* Flexner V in 22 hours, the former in dilution 1/25, the latter in 1/50 These tests were sufficient to rule out the Flexner Y group

2 The results of agglutination tests with patients' sera and three organisms of the series as well as with control cultures are best seen in a table Bacilli B 4, H 3, and S 269 are members of the Sonne III group

TABLE I —*End-points with Patients' Sera*

Organism	Lang	A B	Lyle
Lang	< 25	< 12	< 25
Stewart	< 25 smooth col	< 12, in 5 hours 200 trace, rough col	< 25, in 5 hours 200 +, rough col
A B 3	< 25	< 25	< 25
B 4	80 in 5 hours	Not done	80 in 5 hours
H 3	50 , trace in 5 hours	Not done	Not done
S 269	25, trace	< 25	25, trace

These tests were made at 52° C and were read by hand-lens, except in the case of B 4, which was visible to the naked eye, and where not otherwise stated they proceeded for 22 hours in the water-bath If we leave in the meantime, as suggested above, the reaction of Stewart's rough colony, it is seen that the patients' organisms were not agglutinable by the sera of the patients at the time the organisms were isolated Accordingly, the modified reactions given by the three stock organisms created a difficulty in view of the behaviour of the patients' bacilli, for no doubt at all was entertained at any stage that these latter organisms represented the cause of the outbreak On the very few occasions on which the writer had met with Sonne III bacilli the organisms were agglutinable by the sera of the patients, provided the case was neither chronic nor rapidly fatal It is to be noted that we are dealing with organisms the determination of whose occurrence has been very rare in the West of Scotland, and even in Great Britain and there fore there has been little opportunity to cultivate familiarity with differing properties of different members of the Sonne III group from their isolation onwards Let us now compare with Table I. the behaviour of Lang's bacillus and of the bacillus of A.B 3 with the original specimen of Lang's serum two months after the isolation of the organisms (Table II)

TABLE II.

Lang's serum	Dilutions			Serum control 1/25
	25	40	100	
V B Lang	+	Strong trace	Faint trace	—
V B A B 3	Strong trace	Trace	—	—

TABLE III

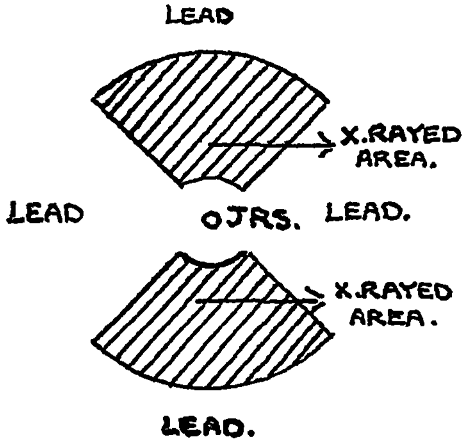
Serum A B	Dilutions		Serum control 1/25
	25	40	
V B Lang	—	—	—
V B A B 3	—	—	—

These reactions were read by hand-lens and were given in four hours They demonstrate (1) that the serum originally supplied and used for the tests of Table I contained agglutinins specific for the organisms of the outbreak, and (2) that organisms which originally gave no response in agglutination tests became agglutinable after a period of residence on an artificial nutrient medium to a square radium capsule for 30, 45, or 50 minutes The capsule used was 1 8 cm square, was screened by 0 2 mm of silver and contained 30 mg $RaBr_2$ $2H_2O$. At half-time it was turned through an angle of 45 degrees so that the irradiated area might be more or less circular In some cases control tumours were grown in the same rats, in others in different rats, but in either case the control tumours were always on the average the larger (See table) A single exposure of 30 minutes produced epilation and permanent loss of pigment in the hair

---

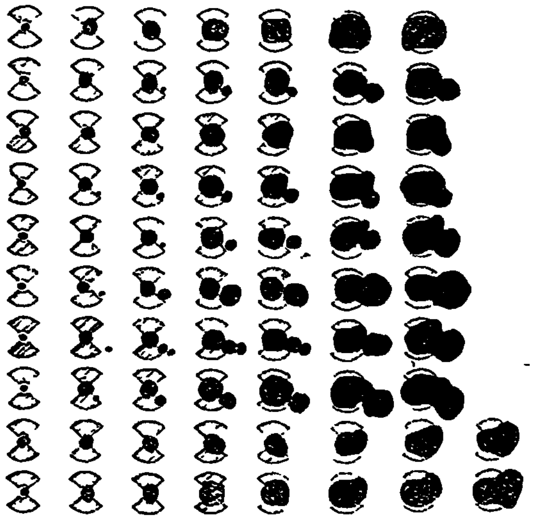
[1] Sonne, C Centralbl f Bacteriol., Orig, 1915, lxxv, 408

FIG 2



In one experiment the capsule was screened with 1 mm of aluminium, and the length of the exposure increased to 60 minutes The silhouettes in Fig 1 correspond to one-seventh of the actual sizes of the tumours 26 days after inoculation, the volume of the tumours in the irradiated areas was 0 52 that of the controls

FIG 4



Preferential growth of tumour into non irradiated tissue

All these observations on more than 100 rats suggested that irradiation of the skin distinctly hindered the growth of the tumour, but this point was tested in a more exacting fashion

Final Experiment

Each rat was covered with lead (2 mm thick, enough to stop the X rays used in these experiments), except for two areas the actual size of which is given here (Fig 2) The rats were then exposed to measured doses of X rays while under an anæsthetic In some cases they were inoculated with J R S before the X ray exposure, but in most cases this was done three or four days afterwards, as nearly as possible into the middle of the screened area directly between the two exposed sectors

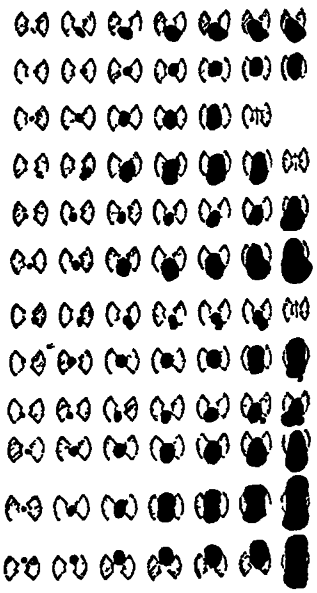
Measurements were taken and charts made on squared paper twice a week, the charts all showed the same tendency, the J R S grew much more readily in the normal than in the irradiated areas In many cases where the irradiated area was eventually invaded by the tumour the growth was much flatter than in the normal regions

The following series was carried out, Figs 3 and 4 only being reproduced here —

	Exposure to X rays	Subcutaneous inoculation
(Fig 3)	30 minutes	3 days later
(Fig 4)	20 ,,	,, before
	45 ,,	,, later
	30 ,,	,, before
	45 ,,	,, 1 month later

All the rats in these experiments were inoculated in the flank, normally J R S in this position grows more or less spherically with a tendency to track into the axilla and *towards the chest*, one X rayed sector was between the nodule and the axilla, and the others directly below it The tumour grew more readily towards the chest and avoided the X rayed area ear the axilla (vide Figs 3 and 4), so another batch of rats was inoculated and irradiated for 30 minutes, and the X rayed areas turned towards the chest and back The results of this experiment are charted in Fig 5, and show that there is exactly the same thing happening, the tumour growing much more readily in the normal tissues than in the X rayed, irrespective of the position

FIG 5



Preferential growth of tumour into non irradiated tissue

The X rays used in all these experiments were generated from a Coolidge tube, with an alternative spark gap of 5 cm between spheres 5 cm diameter Under the same conditions of output and distance it takes about 50 to 55 minutes to give a lethal dose to J R S, the effect of doses of 20 to 45 minutes on the skin ranges from partial epilation to slight blistering

---

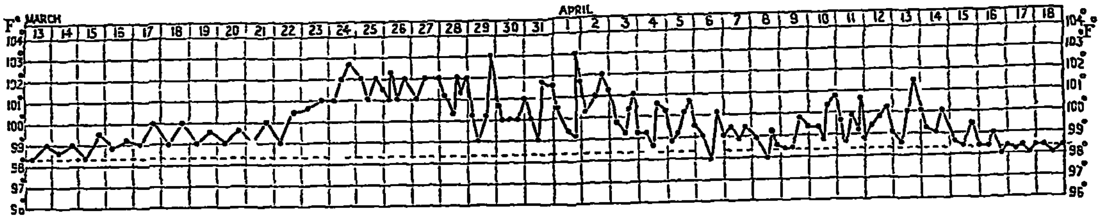
THE SUFFOLK HOSPITAL —Last year the East Suffolk and Ipswich Hospital Contributory Scheme produced over £14,000, an increase of 79 per cent over the preceding year Land has been purchased for the enlargement of the West Suffolk Hospital at Bury St Edmunds Owing to pressure the same ward has to be used for medical and surgical cases, there are insufficient beds for female patients, and the out-patient accommodation is declared in the annual report to be "grossly inadequate"

DIMINUTION IN VENEREAL DISEASE IN BIRMINGHAM The medical report for last year of the Birmingham and Midland Hospital for Skin and Urinary Diseases states that the number of patients with venereal diseases again shows a diminution This is largely due to a striking decrease in the prevalence and severity of such diseases The report adds that in the whole of the Midlands there appear to be fewer than 30 beds permanently allocated to skin diseases, a number which is "pathetically insufficient"

1–2000 Against *Bacillus typhosus* and *paratyphosus* A, B, and C, the reactions were completely negative. Cultures made from the urine were negative

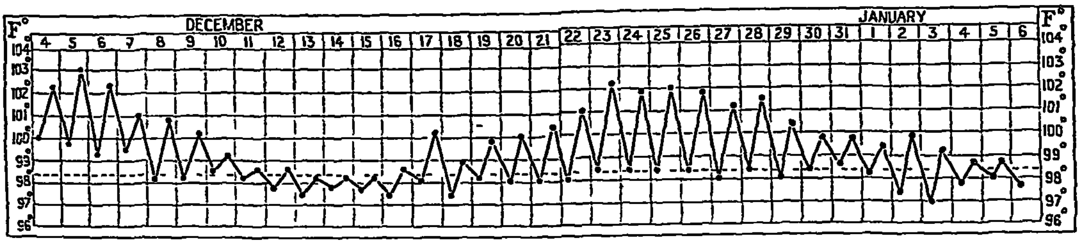
A record of the temperature from March 13th to May 3rd was obtained and the greater part of this is shown in Fig 1 The undulant character of the fever is not well shown. During the pyrexial period the pulse-rate varied between 96 and 120 Within a few days of admission to the nursing home the symptoms abated, on April 16th the temperature fell to normal and remained so until her discharge on May 3rd There was, however, a somewhat protracted convalescence and it was not until the end of June that the patient was able to resume her normal life

FIG 1 (CASE 1)



CASE 2 is that of a man aged 40, a market-gardener, who lived in a small village in Kent He had served in France during the war but otherwise had never been abroad There was no history of any previous illness suggesting undulant fever In March, 1926, he had an attack of influenza with physical signs at left base suggesting early pneumonia, but no consolidation supervened The undulant fever appeared to commence insidiously, for, during the summer of 1926, he began to feel unwell until, on Nov 10th, he suddenly collapsed He complained of fever, severe pain in the small of the back, and a throbbing headache After several days he recovered and was able to resume his work On Dec 4th, however, another attack of fever began and, as is shown in Fig 2, the temperature rose and fell until Dec. 12th. It remained normal for five days until Dec 17th, when another attack commenced This continued and on Dec 31st, when the attack had almost subsided, he was admitted to a nursing home under the care of Dr A. E Russell

FIG 2 (CASE 2).



On admission he complained of a general feeling of fatigue and weakness, pain in the small of the back, and sweating, which was not excessive No physical signs were discovered on examination, and there was no enlargement of the spleen. A blood examination done on Dec 31st gave the following result hæmoglobin, 84 per cent, total red cells, 5,550,000, total leucocytes, 3960, with polymorphonuclears 47 5 per cent, lymphocytes 39 per cent, large hyalines 12 per cent, and eosinophils 1 5 per cent A blood culture done on the same date proved sterile, but the agglutination reactions showed positive results against *M melitensis* to 1–1000 and against *B abortus* to 1–2000. Against *B typhosus* and *paratyphosus* A there was positive agglutination in a dilution of 1–25, but completely negative against *B paratyphosus* B and C, these results being attributable to previous inoculation with T A B vaccine. Cultures made from the urine were negative The symptoms gradually abated and the temperature fell to normal on Jan. 5th, 1927, and remained so until he left on Jan 21st, since when there is no history of any recurrent attack.

The clinical course of each of these cases, the results of the blood examination, and the serum agglutination reactions suggest strongly a diagnosis of undulant fever I regret that in neither case was a positive culture obtained either from blood or urine, but in each case my only opportunities occurred almost at the termination of the disease In the event of failure to isolate the causative organism, no real differentiation between an infection due to *M melitensis* and one due to *B abortus* is possible Such evidence as there is, however, would indicate that both were cases of *B abortus* infection The antiserum prepared in the laboratory against *M melitensis* antigen agglutinates *M melitensis* to a titre of 1–2500 and *B abortus* to 1–1500, whereas the sera from both patients agglutinated *B abortus* to a higher titre than *M melitensis* Both patients drank cow's milk obtained from farms in their immediate vicinity and in both cases there was a vague history of abortion amongst the cattle, but confirmation could not be obtained In neither case was there any history of goat's milk being taken, nor were there any goats in the surrounding neighbourhood

I wish to express my thanks to Dr Box and to Dr Russell for permission to report these cases

---

A CASE OF
MENINGITIS ASSOCIATED WITH *B PROTEUS*

BY GEOFFREY BEWLEY, M D DUB,
PHYSICIAN, ADELAIDE HOSPITAL DUBLIN,
AND
ERIC S HORGAN, M D DUB,
DEPT OF BACTERIOLOGY, DUBLIN UNIVERSITY

CASES of meningitis or other acute infections due to *Bacillus proteus* seem to be extremely rare A recent article by Neal [1] deals with meningitis due to organisms of the *coli* group, but no mention is made of *B proteus*, it being presumably considered outside this group The only cases we can find recorded of virulent *proteus* infections are one of *B proteus* septicæmia in man [2] and one of *proteus* meningitis in an infant [3] In addition Anderson [4] has recorded two cases of typhus fever, in which *B proteus* (apparently of the same strain) was isolated from the cerebrospinal fluids, but as meningitis was not present in either case the significance of this finding is doubtful.

The following case presents several points of interest in this connexion

Clinical History

The patient, a boy aged 13 years, had always been healthy until Nov 23rd, 1926, when he developed a headache which gradually became more severe Four days later he started vomiting and was unable to take any food, and on the

These facts having been established, it was important to return to the serum of A B (the farmer and distributor of the milk who, however, was *not* known to have been a sufferer), and to test the two months' old cultures with it as originally supplied (Table III)

The minus sign means no reaction Tests read by lens after four hours in water-bath and overnight on bench These results confirmed the negative findings with the stools of A B and, excluding accidental contamination of his hands and clothing by other members of the household, were sufficient to declare him free from infectivity These last tests, again, served to discount the reaction given by Stewart's rough colony in Table I , for serum A B would otherwise now have been agglutinating, say, *B* " Lang "

3 Relations with immune sera prepared from different strains of Sonne III bacilli three sera were used, called here S 269 H 5, and D (*a*) Agglutination results obtained early in the investigation are shown in Table IV

TABLE IV —*End-points with Immune Sera*

Organism	S 269 (titre 12,500)	*H* 5 (titre 5000)	*D* (titre 12,500)
Stewart (" rough ")	3000	< 500	Not done
Lang	< 500	< 500	< 500
Arneil	< 500	< 500	< 500

500 was the lowest dilution used, the readings being made by lens after four hours at 52° C

(*b*) 1 Agglutination results obtained after the organisms had been on artificial media for approximately nine weeks the bacilli of Stewart (" smooth "), Arneil, Lang, A B 2 and A B 3 were each agglutinated by Serum S 269 to full titre—namely, 12,500—the serum controls being negative in each case in 1/25, and the results read as in Table II All the flocculations were very fine, an appearance not uniformly given by all members of the Sonne III group

(2) *Saturation Experiment* —The aim of the experiment is to ascertain whether any of our organisms is able to withdraw from a Sonne III immune serum practically all its power to agglutinate the bacillus used to prepare the serum, and incidentally other bacilli of the same group For this purpose serum S 269 and bacillus A B 3 were used, and the results of the tests are shown as fractions The numerator *represents the end-point of agglutination* with the treated serum upon the organism named, the denominator that with the untreated serum Serum S 269 saturated with bacillus A B 3—

On S 269 $\frac{250}{12,500}$

On M 2 $\frac{250}{12,500}$

On S 268 $\frac{250}{12,500}$

On H 5 $\frac{125}{12,500}$

The lowest dilution used was 1/125 It is seen that absorption of agglutinins is for practical purposes complete The experimental results now presented are sufficient to demonstrate that the organisms causative of this outbreak are to be placed as members of Group III of Sonne's classification of dysentery bacilli

Comments

The occurrence in this country of the type of organism we have been dealing with has hitherto, so far as we know, been rare Of course, it is easy to conceive that if met with it might readily have been taken *to be an inagglutinable or atypical* Flexner bacillus A report of the Medical Research Council for 1920[2] states that the type had not yet been recognised in this country One of the main objects in making this communication is to emphasise the possibility of the occurrence of inagglutinable forms of this organism, when there may be some *hesitation* and delay in naming the species

But administrative action is by no means conditioned by such delay For this purpose the naming *of species is of secondary moment* During the period when no serological information of a convincing kind was forthcoming, a report was made to the administrative authority, the conclusion of which was as follows " The organisms of the present series do not so far appear to be distinguishable by cultural methods from the Sonne III group Briefly, the grounds on which it is held that the organisms of our series were causative of the outbreak are as follows (1) they are of a dysenteric type , (2) to the minutest details they are all identical, possessing certain cultural characters which, were it not that these are also possessed by the Sonne III group and by it only, might be described as almost if not quite unique, (3) although they are of quite uncommon occurrence, they were cultivated from the specimens submitted with *a striking, almost processional regularity* " Thus in the presence of, and in spite of a temporary difficulty that the bacteriologist may find in giving a name to certain strains of this group the grounds and modes of administrative procedure, so far as the laboratory can indicate them, are really as satisfactory and abundant as they would be if the organisms had furnished all the data usually considered necessary for scientific classification

Any epidemiological facts relative to the outbreak as it actually happened were furnished by Dr A Johnstone, Health Department, Dumbarton, as factors bearing on the bacteriological work, and I am indebted to him for any facts of this kind which may have necessarily appeared in the introduction to this communication

Clinical and Laboratory Notes.

TWO CASES OF UNDULANT FEVER OCCURRING IN ENGLAND

BY J BAMFORTH, M D LIVERP , M R C P LOND ,
ASSISTANT BACTERIOLOGIST ST THOMAS'S HOSPITAL.

IT has recently been pointed out by G S Wilson and Muriel M Nutt[1] that *Bacillus abortus* is frequently present *in cows' milk* in certain *English* counties. The possibility of human infection from this source is therefore of some importance Cases of *B abortus* infection in man have been described in various parts of the world by different authors and the following records may prove of interest

CASE 1 is that of a woman aged 63, who had never been abroad and was domiciled in London In July, 1925, she went to live in a small village in Essex and remained there until Christmas, only occasionally coming to London for business purposes She stated that her illness commenced about the end of November, 1925 She was unable to concentrate on her work and felt tired and ready for sleep There was loss of appetite and the feet became swollen and tender On her return to London in June, 1926, she became much worse and experienced severe headache, sore-throat, and frequent attacks of shivering and perspiration These symptoms continued and, in addition, there was considerable abdominal discomfort from flatulent distension The attacks of perspiration persisted and were accompanied by a rise of temperature in the evening

On March 31st she became a patient in a nursing home under the care of Dr C R Box Palpation of the abdomen showed a certain amount of tenderness in the epigastrium There was no enlargement of the spleen A blood examination done on April 1st gave the following results hæmoglobin, 62 per cent , total red cells, 5,310,000 , total leucocytes, 6250 per c mm , with polymorphonuclears 34 per cent , lymphocytes 62 per cent., and large hyalines 4 per cent. Blood culture and agglutination tests were done on the same day The blood culture proved to be sterile, but the serum *showed positive agglutination* against *Micrococcus melitensis* to a titre of 1–1000 and against *B abortus* to

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

GENERAL MEETING OF FELLOWS

A SPECIAL general meeting of Fellows was held on April 7th, Sir STCLAIR THOMSON in the chair, when Mr W G SPENCER opened a discussion on

BLOODLETTING

The subject. he said still lay to some extent under the cloud of prejudice handed down from the days of general disuse of venesection Under certain circumstances it might be the sole means of saving life but further evidence was needed to establish the indications for more chronic conditions The discovery of the circulation had had no influence upon the practice of bloodletting which had been discarded 300 years later, owing to the revolution in the art of diagnosis Mr Spencer then reviewed the history of the procedure among the ancient and mediæval physicians Some of the influential members of the profession who had put forward opinions directed towards the disuse of bloodletting had been John Hunter, Marshall Hall, P. C A Louis, Hughes Bennett, James Paget and Benjamin Ward Richardson Impairment of the pulmonary circulation was the capital indication for bloodletting Experiments on asphyxia had shown that the blood became more viscous and that less and less venous blood reached the left auricle and the myocardium which was thereby reduced in activity At the point when respiration had ceased, although the heart was still beating venesection to an extent sufficient to cause a sudden fall of blood pressure in the pulmonary circulation produced afferent impulses, transmitted by the vagi to the respiratory centre and there was also a rapid withdrawal of fluid from the connective tissues back into the blood which thus became less viscous Mr Spencer referred to a number of cases recorded by Henry Sutton Pye-Smith and others more recently. in which venesection had saved life The conditions included passive congestion of the lungs. cardiac disease with failing circulation air embolism following artificial pneumothorax scarlatina, nephritis bronchitis and suffocative catarrh. ' apoplectiform seizures status epilepticus, and heat-stroke J S Haldane and his colleagues had pointed out that artificial respiration in cases of asphyxia might fail because apnœa had been set up In such instances venesection might start spontaneous breathing by afferent excitation of the respiratory centre Bloodletting had also been used effectively in acute alcoholic delirium and methæmoglobin. carbolic, and mushroom poisoning In young children it might be difficult to open a vein and some workers had adopted radial arteriotomy

Small quantities of blood could be conveniently extracted by cannulæ lubricated with an anticoagulant Venesection served as an adjuvant to drugs in promoting sweating expectoration, purgation urination, and sleep The pain of aneurysm and the headache of high blood pressure were relieved Polycythæmia of the type resulting from overproduction of red blood corpuscles was the one kind in which venesection was indicated Animal experiments had proved that after the first bloodletting there was increased activity of the bone-marrow and letting a few ounces of blood had been advocated by many practitioners for chlorosis The speaker had once seen a case so treated by Dyes

Dr HERBERT FRENCH dealt with the value of bloodletting in two types of chronic case Rare. but not so uncommon as was thought was splenomegalic polycythæmia, which he had seen treated in many ways but never so much benefited as by bleeding at regular intervals Nor did cases ever do badly under this treatment

More common, but difficult to define were cases among busy overworked intellectual men, who took too little exercise and who gradually found, somewhere between 45 and 55 that their brains would not work so well they felt giddy in the mornings, a little "swimmy" and so on This type of case was apt to get included with the high blood pressure group but hyperpiesia was not an essential feature of the clinical picture and bleeding gave relief regardless of whether it reduced the blood pressure or not The benefit was measured by the patient's own feelings, he felt better while it was being done. was much more active afterwards and returned spontaneously for another venesection In women the same kind of trouble with vague feelings of fullness in the head usually occurred about the menopause. Such patients invariably benefited by bloodletting. and the reason seemed to Dr French probably to be that there were times when the destruction of red blood cells did not continue as speedily as it should so that there was a banking-up in the system. If a pint of blood was removed a fresh pint was soon supplied and so the circulation was renewed Dr French then illustrated the simple and satisfactory "needle and bottle" method of removing blood The special needle differed from ordinary needles in being part of a cone and not of a cylinder. so that it caused very little pain and never allowed clotting

Dr FORTESCUE FOX said that the value of venesection had been brought home to him by a case of thoracic aneurysm Before means had been devised for estimating the blood pressure venesection had been used for all obvious emergencies of the circulation; cyanosis was relieved and the arteries became reflexly relaxed in pulmonary and cardiac cases thoracic tumours, carbon monoxide and other poisoning. Many remarkable cases of patients bleeding themselves in circulatory emergencies had been put on record. Cases of heatstroke demanded large venesections

Health seekers at spas said Dr Fox were not so much ill as candidates for illness and amongst such cases venesection had another field of equal or even greater usefulness Sometimes the sudden ingestion of water was in excess of elimination and. since the functions of elimination were commonly defective. the danger of plethora was by no means negligible A preparatory venesection or course of purgatives was often wise before taking the waters There were two types of hyperpietic the jovial florid, and plethoric individual and the more serious pale. anxious-looking one In both spontaneous hæmorrhage might occur from nose or uterus or profuse watery evacuations and symptoms were thus relieved Hyperpiesis and nervous hypertension were in most cases the transient disorders of an epoch, and many patients passed in time out of the danger zone The behaviour of the vessels shewed that the essential factor was hypertension—a disordered nervous and circulatory function Venesection might or might not cause a fall in blood pressure In many women a course of sedative baths after the menopause was preferable to venesection

Death from apoplexy in the fifties and sixties appeared to be increasingly common among brain workers and could often be prevented by venesection when the blood pressure began to rise Dr Fox suggested that many failures occurred because preventive measures were not bold enough and were taken too late His practice was to combine substantial periodical venesection with fasting in bed and a course of sulphates a regime which could be repeated if necessary every two or three months He had used the method in cases of more or less advanced cardiovascular degeneration as he could not believe that the high pressure was a desirable compensation for increased peripheral resistance the pressure was attributable to exaggerated tonus rather than to degenerative changes The vessels after long contraction would often in fact, resume their natural size under suitable treatment In many cases of atheroma of the aorta the blood pressure was liable to periodical and dangerous increase morning of Nov 29th he became unconscious and was brought to hospital

When first seen by one of us (G B) he was unconscious and could not be roused He was thin, pale, and had a coated tongue, his bowels not having moved since the onset of the attack, and his temperature was 101° F His head was retracted and his neck muscles stiff His pupils were dilated and did not react to light His knee-jerks were increased, but there was no ankle-clonus, and the plantar reflex was normal Kernig's sign was present and there was retention of urine A lumbar puncture was performed and 20 c cm of cerebro-spinal fluid drawn off under considerable pressure The fluid was slightly greenish in colour, very turbid, and contained an enormous number of polymorphs A portion of the fluid was sent for bacterial examination to one of us (E S H), who reported that a direct smear showed a very few Gram-positive diplococci Accordingly antipneumococcal serum was at once injected into the cisterna magna

Next morning the clinical condition was unchanged, except for the temperature having dropped to 99° F The bacterial report was received that a Gram-negative bacillus had grown from the fluid and was probably a contamination A second cisternal puncture was performed, the fluid was drawn off for another examination and more serum was injected On the following morning the patient's condition was worse, his temperature being 101° F and his pulse weak A third intrathecal injection of serum was given , but the temperature continued to rise, and in the afternoon it reached 108° F just before death supervened

No post-mortem examination of the body could be made

Laboratory Findings

When the first specimen of lumbar fluid was received direct smears (Gram stain) were made in addition to culture on blood-agar and glucose broth A careful search of the smears in addition to the numerous pus cells revealed what appeared to be Gram-positive diplococci—very few in number—and a provisional diagnosis of pneumococcus was made However, both liquid and solid media gave pure cultures of a Gram-negative bacillus There were only a few colonies on the blood-agar plates, although the purulent fluid had been spread thickly, and this perhaps accounts for the failure to find the bacillus in direct smears This was thought at first to be merely a contamination, but the second specimen of the fluid gave exactly the same organisms Examination for the tubercle bacillus was negative in both cases

The characteristics of the above organisms were as follows A Gram-negative motile bacillus morphologically resembling *B coli* The colonies on agar were large, white, and confluent, and grew in a series of concentric waves In broth there was a general turbidity with a putrid odour There was no hæmolysis on blood-agar

Fermentation Reactions—Acid and gas on glucose and lævulose , no change with maltose, mannite, dulcite, lactose, and saccharose Indol was produced in faint traces (Ehrlich's reagent) on a special peptone (difco) broth after several days' growth, but was not found when ordinary tryptic digest broth was used Gelatin was liquefied

The classification of the *proteus* group based on either fermentation reactions or indol production is extremely unsatisfactory at present, but the above organism corresponds fairly closely to *Proteus mirabilis* in Bergey's classification, or into group I according to Besson

In our opinion the Gram-positive bodies seen in the smears were certainly artefacts, such as are often seen in films containing pus It seems impossible to believe that they could have been living pneumococci, as we have never failed to grow such (from cerebro-spinal fluids) by inoculating it liberally into glucose broth It may be argued that these were dead pneumococci, but in this case some signs of clinical improvement would have been expected, and it is hard to see how they could have disappeared completely from the cerebro-spinal fluid in the 24 hours between the two punctures

On the other hand, it is difficult to state with certainty that the *proteus* organism was the cause of the fatal meningitis, but the fact must be significant that it was isolated in pure culture on two successive occasions

A CASE OF IODISM

BY MATTHEW MASSER, M B , CH B LEEDS.

THE following case has several interesting features.

An ex-soldier, aged 31, who was receiving a pension for war nephritis, came to me complaining of persistent headache, general malaise and debility, gastro intestinal discomfort, and poor appetite Examination showed him to have albuminuria and high blood pressure, to which his symptoms were attributed

He was put on a low protein and nuclein diet, and was given gr 5 potassium iodide three times daily Four days later I was called to his house The patient was in bed and complaining of severe running from the nose, inflammation in the right eye, and a swelling on either side of the neck Examination showed conjunctivitis of the right eye and coryza, an acutely injected and œdematous throat, and a painless bilateral cervical adenitis The tongue was thickly furred The chest was normal and temperature was normal There was no rash visible, nor was there any history of chill

The symptoms were apparently due to iodism, as they rapidly subsided on the cessation of the iodides The interesting features of the case are the painless cervical glandular enlargement, which was the most prominent of the patient's symptoms, and the possibility of the toxic symptoms being due to defective elimination of iodides by the damaged kidneys

A CASE OF
POST-MORTEM CÆSAREAN SECTION,
WITH DELIVERY OF A LIVE CHILD

BY I R ROSIN, M B , B CH DUB.,

HOUSE SURGEON, THE INFIRMARY, BURY

THE following is a brief account of a somewhat unusual case

Mrs L K , aged 30 years, was admitted as an emergency case to Bury Infirmary on June 28th, 1926, in a state of unconsciousness

That morning at 6 o'clock her husband had gone off to work as usual, leaving her asleep in bed At about 9 15 A M it appears that "she got out of bed and fell heavily to the floor in a queer condition," according to the little daughter who immediately called in a neighbour The latter, knowing her to be pregnant and "expecting shortly," called in the midwife, who immediately sent for a doctor The medical man ordered her removal to hospital, where she was put to bed , but within a few minutes of her admission, while she was being examined, the faint trace of life still present flickered out

Although realising that the patient was dead, I persevered for 15 minutes in an attempt to resuscitate her by artificial respiration and administration of oxygen, and hypodermic injections of strychnine, digitalin, and pituitrin All these were of no avail

Palpation of the abdomen during this time revealed tumultuous movements on the part of the fœtus and the fœtal heart could be heard beating at the rate of 156 beats per minute Under the circumstances, I decided to perform Cæsarean section and delivered a full-time male child—in a state of asphyxia livida—a quarter of an hour after the mother's death Twenty minutes of artificial respiration and alternate immersions in hot and cold baths revived the child and he cried lustily He weighed 7¾ lb , and has since made normal progress

At the post-mortem examination of the mother, the liver was found to be enlarged and studded with small hæmorrhages , the spleen and kidneys were acutely inflamed, and the heart muscle was soft and showed signs of fatty degeneration The brain, on removal, appeared perfectly normal, but it was found that the entire left lateral ventricle was filled with a large recent blood clot

I am much indebted to Dr J C Turnbull, honorary obstetric surgeon to the Bury Infirmary, under whose care the case was admitted, for permission to publish these details

Sometimes only a short stay in hospital could be arranged, and perhaps when the patient left she was no better than when admitted. Crises occurred from time to time, and as a result the general plane of health was lowered Here operation was most helpful It was necessary to take the long view and patients must realise that this condition began gradually, went on for a long time, and therefore improved only slowly All cases should be carefully watched; he had found cardiac failure, glycosuria and mental trouble develop even while subjects were occupying hospital beds Sometimes visceral or cerebral intoxication dominated the picture Of 910 patients with exophthalmic goitre on whom he had operated, 61 had had established auricular fibrillation for months, some of them for years Many had continual œdema well up the body, and fluid in the abdominal cavity, their mental state being such that they could not be kept in their own homes

Safety and Efficiency of Operation

The origin of Graves's disease, said Mr Dunhill, was not necessarily in the thyroid gland, but it was the secretion from that gland, acting as a circulating poison, which damaged the viscera When medical treatment did not seem to have succeeded, the intoxication should be lessened by operation, which could be made safe by ensuring that the patient had no load to carry besides the disease Even at the present day patients who had gross sepsis were sent for surgical treatment Such conditions as abscess at the root of a tooth or septic tonsils did more damage to patients with Graves's disease than to ordinary people Everything which reduced the reserve of health should be eliminated before surgical intervention was considered, and operation should be prefaced by sufficient rest in bed and preparation of the patient If operation were attempted on the day following admission many patients would die Several days were needed for the pulse to come down to its resting level under quiet and absence of worry After this resting level had been reached iodine medication should be carried out; it would bring that level lower still and induce a change in the pathological condition of the gland which made the operation safer still At the operation itself the amount of interference must be governed by the patient's strength There was a temptation to get the operation over at one sitting, but it must be remembered that these patients were not subjected to operation until they had been ill a long time When cardiac lesions and œdema were present safety could only be ensured by the closest cooperation between physician and surgeon

As an anæsthetic in these cases Mr Dunhill regarded chloroform as absolutely unsafe Open ether was safe but it was inconvenient to have a mask over the chin Local anæsthesia gave a comfort in work and a freedom from bleeding which were otherwise unattainable Indeed, when auricular fibrillation was present he considered local anæsthesia essential Unless moribund, most patients stood the operation if these precautions were taken The removal of the first lobe was a comparatively easy matter, the difficulty lay in the taking away of the right amount of the second lobe In this second stage the approach had to be made through scar tissue the anatomical planes having been a good deal destroyed by adhesions Moreover a very vascular gland had to be cut through Unless the surgeon was prepared to carry through this second operation he should not attempt the first Enough of the gland must be removed to eliminate the toxic effects of the secretion always remembering the physiological needs of the body The death-rate following operation would vary within wide limits according to the type of patient, the time selected for operation and the care with which the preliminary treatment had been carried out Some surgeons would not operate on patients who were very ill because of the risk of spoiling their statistics If all cases requiring surgery were operated on the mortality-rate he thought, could not be brought below 3 per cent

In a large series of cases mental disorder was not infrequent Some patients suddenly became maniacal and died In the presence of mental symptoms he had never operated until the relatives fully appreciated what was at stake and it was well to have the help of an alienist before deciding to employ surgery People who had had Graves's disease in marked degree never, he thought became quite normal again, though the removal of a large part of the gland often brought about dramatic relief These patients if possible should not resume the hard work to which they had previously been accustomed.

The Medical Aspect.

Dr C M WILSON endorsed what had been said about the selection of cases for operation Cases of toxic adenoma should be operated on because the surgical risk was much less than in ordinary exophthalmic goitre and medical treatment was unsatisfactory Auricular fibrillation was also an indication for operation, as presumably the physician had been unable to restore the normal rhythm by digitalis In the remaining group however—namely, those in which, after six months of medical treatment, the pulse-rate remained over 100 and medical treatment was considered to have failed—a much closer examination of surgical claims was called for In many of these cases he thought, medical treatment had not been properly tried Mere rest and bromides could not be called medical treatment If it had been properly tried and had failed and something more was necessary, was that "something more" surgery, or was it X rays? In the best hands, the mortality of surgery in exophthalmic goitre varied between 2 9 and 5 per cent, the mortality after X rays was nil This comparison justified a very careful consideration of the claims of X rays, and in suitable cases their effects should be given a trial

To place a patient with exophthalmic goitre in a hospital ward was not necessarily to give her proper rest continued Dr Wilson There might be someone slowly dying in the next bed, or disquieting details might be taught to students over a patient near by It was doubtful whether hospital conditions were suitable for the medical treatment of these cases; what they needed was a quiet place in the country. Sepsis certainly played a part in the disease, but though it should be removed if found it should not, he thought, be imagined Minor operations had a bad effect on these patients An ordinary diet was not of any disadvantage For auricular fibrillation the digitalis should be pushed No one could tell for certain which cases would respond well to X rays, but very severe and acute attacks were unfavourable for their use So were cases in which the goitre was large, but the milder cases responded much better. X rays should be tried over a period of six weeks, at the end of which time any response would be evident It was well to have the basal metabolic rate of the patient estimated, so that the ray treatment should not produce myxœdema

Iodine, said Dr Wilson, was the fashion of the moment It was useful in preparation of the patient for ten days prior to operation, and also in combating crises, but it had not yet been proved of value in the routine treatment of the disease Unless its administration was accompanied by daily observation it was capable of doing much harm The mental factor was very important Surgery should be reluctantly employed as it often meant removing from a young woman three-fourths of a gland which was valuable physiologically leaving her with one-fourth in a condition of hyperactivity This residue might suffice for her needs while it remained over-active, but would it be enough to carry her through later, especially if she became pregnant? The success of surgery depended on the skill of the surgeon the preparation of the patient and the choice of the best time for the operation

The Time and Nature of Operation

Mr. C A JOLL discussed the suggestion that operation should always be deferred until six months

No little discrimination was needed in selecting cases for venesection He agreed with Dr French on its value in patients with flushing, heat and throbbing in the head without serious rise of blood pressure

Sir William Hale-White spoke of the enormous numbers of people bled every spring in past years, and said that the most striking thing he knew in the history of medicine was this abrupt change In 1840 a practitioner had been accused of malpraxis because he had not bled a case of pneumonia Cases of all sorts had been bled for no particular reason that we could see now except that it was the fashion Apart from tragedies due to loss of blood, many patients died of pyæmia from septic venesection wounds Nowadays the case above all others that called for bloodletting was the one in which the right heart was overwhelmed, and the guide was "Is the patient livid ?" The dilated right heart was in the condition of a paralytic bladder, and until it was emptied directly it could not contract and the patient would do badly Digitalis was often found to act much better after venesection than it had before Most pneumonias were not livid, and so did not need it In apoplexy it was important to choose the case which was one of embarrassment of respiration —again shown by the livid face Venesection was of immense benefit in those few cases of status epilepticus where convulsions predominated so that the patient was livid It was not of much permanent use in uræmia unless the patient was very livid, little poison would be removed from the system by withdrawing a pint of blood It relieved the pain of aneurysm and was undoubtedly valuable in polycythæmia where the total volume of the blood, as well as the number of corpuscles, was increased, where the condition was in fact an "innocent tumour of the blood" In cases of high blood pressure there was much to be said on both sides Two practical points might be noted the patient should always be bled sitting up, so that if he fainted he could be revived by lying down, and great caution should be exercised in bleeding the young and the very old, who stood it badly Arteriotomy had gone out of fashion, and leeches and wet cupping were ineffective

Dr J F Halls Dally mentioned further points in the history of the practice, and agreed with Dr French and Dr Fox that it was useful in high blood pressure, though depending less on the height of the pressure than on the symptoms The relief given by venesection was, however only temporary, and for real benefit should be combined with treatment by starvation for periods from 24 hours upwards and with general lowering and depleting measures

Sir James Dundas-Grant quoted successful cases in his own practice of the use of venesection in uræmia following scarlatinal nephritis, in asphyxia from drowning, in puerperal eclampsia and uræmia, and in post-operative congestion when hæmorrhage into the wound was threatened

Fleet-Surgeon W E Home described venesection in hospital practice in Edinburgh in 1841 Of the three leading physicians of that time Allison treated his "fever" cases with wine and opium, Henderson gave them nothing at all, and Craigie bled them There was no difference whatever in the mortality, but Allison's patients had a quick convalescence Henderson's had a long one, and Craigie's had a "protracted, painful, and terrible" one

Sir William Willcox thought there were five classes of case which benefited by venesection The first was that of right heart dilatation He thought that insufficient importance was attached nowadays to percussion; dullness in the fourth right space was a valuable indication of the size of the right auricle The second class was convulsive, including status epilepticus and uræmia Cases of chronic nephritis did not do well, but where the kidney was only temporarily incapacitated from function as in eclampsia and trench nephritis bleeding stopped the convulsions In the third class came heat-strokes, that the benefit was not due merely to removal of toxins was shown by the fact that if normal saline were introduced after the bleeding the convulsions were started all over again Polycythæmia was the fourth type of case, and the fifth he described as medico-legal—patients with violent asphyxia—e g, due to drowning or hanging He thought that Dr Fox's scheme of timely venesection in cases of high blood pressure was admirable Bloodletting was a form of treatment of the utmost value in certain cases and ought to be practised more than it was to-day

Dr H Letheby Tidy said that all were agreed that blood should not be let for anæmia or conditions of low blood pressure Much of the discredit which had fallen upon the practice was probably due to the error of applying it for those low pressure conditions which simulated high pressure—e g, cerebral thrombosis All were agreed also on its value in polycythæmia, in high blood pressure as described by Dr French and Dr Fox in sunstroke and in acute dilatation of the right heart with lividity There appeared to be two uræmic groups that mentioned by Sir William Willcox where venesection should be done and those more chronic cases described by Sir William Hale-White where it should not be used

Mr Spencer in reply, mentioned the large number of cases of carbon monoxide poisoning occurring at the present time in which only artificial respiration was tried

HARVEIAN SOCIETY.

A meeting of this Society was held on April 7th, Dr E Le Fevre Payne, the President, occupying the chair

Mr T P Dunhill opened a discussion on the

Treatment of Graves's Disease

He had come to regard the treatment of this disease, he said, as requiring the conjunction of the physician and the surgeon Often there came a stage at which medical resources seemed to have reached their limit, and then much could sometimes be done by surgery There had been a time when physicians and surgeons warmly debated on the best treatment—when physicians said that if a case were left alone and given a chance it would get better In this country the position had been reached at which physician and surgeon cooperated going through the wards together realising that these people were very ill, that they had a long and hard fight in front of them, and that sometimes they could be helped in one way and sometimes in another In every case of this disease medical treatment should precede surgical measures, for a long time every case should be regarded as medical The ætiology and pathology should always come into the surgeon's purview It could not reasonably be expected that surgery would always make the patient quite well, and any estimate of the results must be based on her condition before operation Sometimes circumstances prevented the ideal treatment being followed and even under good conditions in hospital wards some patients seemed to lose ground The time of operation must be carefully considered in each individual case It varied greatly according to the progress of the disease and the social position of the patient, but surgical intervention was practically never indicated during the first six months of the disease The onset might be insidious, indeed there must be many people who almost developed the disease but did not quite do so Therefore if exophthalmic goitre were met with in early stages it must be possible to restore the patient to normality Some cases however, began with severe symptoms such as vomiting and diarrhœa

Of 170 consecutive patients on whom he had operated between 1921 and 1925 68 had been suffering from the disease for more than four years 48 for over six years whilst 32 had been very ill over ten years This of course represented a very large total of morbidity and unhappiness as well as economic loss Circumstances often determined anxiety for operation, the patient might be poor and have the cares of a family upon her or she might have to earn her own living constantly. Her blood count was very fair, her blood pressure normal but her urine, though normal in quantity, contained some albumin and casts. She showed little response to treatment by rest in bed, starvation, lavage of the bowel, and purgation. Corpus luteum was given in 1 c.cm. doses hypodermically, with little or no result. The patient admitted that both she and her husband were anxious not to have a child at the time.

Following the practice of Malinin of the Frauenklinik in Saratow, about 25 c.cm. of the patient's own blood was withdrawn from the median basilic vein and was reinjected in six different places. This treatment was twice repeated at intervals of three days. The patient began to improve rapidly. The local parish priest visited the patient at this time and it must remain undecided whether the Church or Medicine was responsible for the successful issue.

CASE 2.—Mrs. B., aged 28, had been married four years, and was seven weeks pregnant. She had had one full-term pregnancy two years before. On admission her general condition was very bad. She showed great fatigue and anæmia, her blood pressure was 116-80, and her pulse-rate 90, the urine was scanty and contained albumin, casts, and acetone, the skin was dry, the tongue was dry and furred with sordes around lips and she suffered from great thirst.

The uterus, which was retroverted, was replaced and a pessary inserted. For the rest the treatment consisted of complete rest, purgation, lavage of the bowel, and rectal administration of sod. bicarb. and pot. brom. Corpus luteum extract proved ineffectual. After about two weeks the patient began to improve and eventually she was discharged cured.

CASE 3.—A primipara, aged 24, was 8 weeks pregnant. The uterus was in the normal position, the pulse-rate was 84, there was slight anæmia, and the urine was scanty, containing albumin, casts, and large quantities of acetone. The patient vomited on making the slightest movement in bed. The usual treatment of purgation, lavage of the bowel, and administration of sod. bicarb. per rectum was given. Corpus luteum had no effect given hypodermically. Irradiation of the hypophysis was attempted.

The first signs of improvement were noticed about 14 days after admission to the nursing home and followed rectal administration of pot. brom. gr. 30 in four ounces of water morning and evening.

Discussion.

The PRESIDENT referred to a previous discussion on hyperemesis in early pregnancy,[1] and to the great stress then laid by Dr. FitzGibbon on the neurotic element and its treatment by psychotherapy. He personally thought that a great many of these cases were toxic in origin. He had administered thyroid extract in a couple of cases but had not found it of any value. Dr. Cassidy was to be congratulated on not having had to induce therapeutic abortion in any of his cases. It was always taught that if starvation, thorough elimination, and rectal enemata did not stop the vomiting in these cases, then pregnancy should be stopped; yet Dr. Cassidy's three cases had all been treated in different ways, and it had not been necessary to stop pregnancy in any of them.

Dr. BETHEL SOLOMONS said that if women were unaware that vomiting occurred in pregnancy, few would suffer from it. Patients were often in doubt as to their condition because they did not vomit although told by their friends that they ought to do so. He was a firm believer in the neurotic or psychological element as an ætiological factor, both in the mild and severe forms of vomiting. Irrigation of the stomach had a good effect in all cases. When done gently it caused no shock, and it had the excellent effect of (1) removing the backflow from the liver, and (2) clearing up hysterical cases because it was unpleasant. It was also useful because purgatives could be left in the stomach, and he was surprised that Dr. Cassidy had not adopted so simple and excellent a form of treatment in any of his cases. He believed, too, in removing such things as basins from the patient's bedside and in putting the patient on a full diet free from all greases. While holding the view that most cases were of the psychological type he had full knowledge that there were some few which were toxæmic and must be treated as such. In the treatment by subcutaneous injection of the patient's own blood it was interesting to note that the sequence of events had been: injection of blood—marked *fright*—cure. It was seldom necessary, he thought, to perform therapeutic abortion.

Dr. GIBBON FITZGIBBON thought that the psychical element in these cases was very strong. Patients got into the habit of vomiting, and thought that they should vomit. While master of the Rotunda Hospital he had found that cases generally responded to starvation elimination and enemata, and he had only had to induce abortion twice. One of these had died even after abortion. These cases seemed to him to respond to all sorts of treatment, and the more he saw of them the more he was convinced of the psychical element in them. He thought there was no reason to believe in the toxic element in hyperemesis. Vomiting was always more severe in the multipara than the primipara. In one case he had tried injecting human blood into the patient, but without any result. There was far too much fear of letting these patients carry on and he thought that pregnancy should be allowed to continue up to the fourteenth or sixteenth week, different methods of treatment being tried till then before abortion was induced.

Dr. D. CANNON asked if any effort had been made by gynæcologists to visualise the mechanism of the stomach in hyperemesis. He had seen two cases in which it had been proved that achlorhydria was present. He referred to work done by Prof. D. P. D. Wilkie in this connexion and also to that of a German investigator who had shown that over-regurgitation of bile into the stomach would cause morning vomiting and other symptoms in pregnancy, and had suggested the administration of atropine sulphate. Dr. Cannon felt that these cases were functional and not toxic. He wondered how a retroverted uterus could cause gastric symptoms and yet he had often found that simple correction of the uterus did effect a cure. An American observer had proved that duodenal stasis was present in hyperemesis.

Dr. G. TIERNEY said that it was difficult to decide which cases were toxic in origin and which were not. He considered that a number of them had a psychic as well as a toxic element. He mentioned a paper recently published by Dr. W. E. Levy, of New Orleans, in which it was stated as evidence of toxæmia that acetone was found in the urine, with diminution in the blood-sugar and in the CO_2 combining power of the blood. The paper reported six cases in or about the fourth month of pregnancy. They had been treated for a time on general lines without success before coming under his care. Then they had been treated with insulin and glucose. One woman, who was four months pregnant, and had been vomiting continuously for three weeks, was in such a state that he thought he would have to resort to therapeutic abortion, but after intravenous injection of insulin and of a 10 per cent. solution of glucose, the vomiting had ceased, so that the patient went on to full term.

Dr. E. HARVEY suggested that the cases which were helped by insulin were those in which acidosis had been the cause of the vomiting. Insulin would not necessarily be effective in other cases in which acidosis was not the cause of the vomiting.

Dr. CASSIDY, in reply, said that he did not think the psychical effect of washing out the stomach would be sufficient to justify the distress which it would cause to these patients. Most of them were of a neurotic type. Generally, vomiting developed about the eighth week and stopped about the sixteenth week: it seemed that the vomiting diminished as the resisting powers of the body increased. Acetone would be found in the urine in any case of starvation and should not be taken as pathognomonic of hyperemesis gravidarum. An increase of bilirubin in the serum was, he thought, a sign that the case might be toxic. From the clinical point of view it seemed that the important thing was to try to distinguish between the toxæmic and the purely neurotic case.

Dr. D. CANNON read notes on a case of retroperitoneal fibroid and a discussion followed.

---

[1] THE LANCET, 1926, i., 76.

had elapsed from the onset of the disease Apart from other considerations, this six months' delay might be very awkward for people who had to earn their living. Usually it was easy to find out in far less than six months whether a patient was likely to get reasonably well He would place the minimal period before decision at three months, and even then it would be nearly 12 months before the patient returned to work It was not right, he thought, to subject patients to a prolonged invalidism Basal metabolism was often loosely estimated, and it was easy for grossly erroneous figures to be reported The patient must be at rest in bed, and must be absolutely quiescent, mentally and physically

With regard to X rays, Mr Joll had looked up 50 consecutive cases which he had seen in private practice, 32 of them had had preliminary X ray treatment, and had only come to the surgeon because the X rays had not sufficed This was generally true throughout the whole range of his cases, X rays caused temporary improvement, but could not be considered curative He doubted whether myxœdema ever followed X ray treatment He agreed that iodine could reduce the pulse-rate and temporarily improve the condition of these patients but sometimes it caused deterioration It was wrong to broadcast the virtues of iodine in the treatment of exophthalmic goitre, as had been done by a section of the lay press

The selection of cases for operation, he agreed with Mr Dunhill, required the fullest cooperation between physician, pathologist, and surgeon, and many cases were best left alone for six months or longer Preliminary double ligation of thyroid arteries had a distinct value, in his opinion—not as a cure, but as a means of minimising the operative risk Open ether anæsthesia did very well for cases of medium severity, but not for the severe, fibrillating emaciated cases, for which he strongly favoured local anæsthesia If this was preceded by morphia and hyoscine, together with a rectal injection of half an ounce paraldehyde in half a pint of saline, the patient remained satisfactorily quiet throughout the operation Not every patient, however, responded well to local anæsthesia, and any restlessness was a disadvantage both to the patient and the surgeon Rectal anæsthesia he had found unreliable

Frequently he had removed seven-eighths of the thyroid gland—on occasion as much as nine-tenths—and he had never seen a trace of myxœdema in the cases What was the standard of cure? He thought that if a patient could return to work and remain at work, with the ordinary holidays, without suffering relapse, she should be regarded as cured, even though some degree of exophthalmos still persisted

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY

AT a meeting of this Society held on April 7th, Dr E RIVAZ HUNT, the President, in the chair, Dr. RODERIC CLAPHAM showed a case of

Chronic Diarrhœa

The patient was a woman aged 37 Two months ago she came to hospital complaining that for three years she had had diarrhœa, and that it had become much worse in the previous six weeks She had about nine motions daily, they were quite painless, and she was losing weight rapidly

Examination of the abdomen and rectum revealed nothing except slight weakness of the sphincters Examination of the nervous system, however, showed that the case was one of tabes The patient had Argyll Robertson pupils, loss of ankle- and knee-jerks, and commencing perforating ulcers of both feet The gait was normal, Romberg's sign was absent, and there was no incoordination There was some analgesia and paræsthesia of the feet, and of the outer side of the legs and the inner side of the arms

Laboratory tests indicated syphilitic infection, and under treatment by Dr F Lawson at the venereal diseases clinic the diarrhœa improved so that the patient had only two actions a day

Dr J. STANLEY ELLIS read a paper on

Ultra-violet Therapy

After giving a brief history of the development of natural and artificial sunlight therapy, he discussed the advantages and disadvantages of both methods and suggested that artificial sunlight bore the same relationship to natural sunshine as synthetic drugs bear to crude drugs The rays had definite photo-electric photo-chemical, and fluorescent effects on the tissues, and these were the basis of profound physiological changes Dealing with the effects of the rays on cholesterol, on the nerve-endings, and on the production of pigment, all of which were claimed as the cause of the beneficial effects of therapy, he pointed out that the various conditions which responded to treatment fell naturally into four or five groups in which the above physiological changes and others were most marked He also stated that certain drugs and endocrine extracts were activated by the rays in the human body, which in itself made it necessary that the physician and actinotherapist should collaborate The use of ultra-violet rays was, *he said, in danger of discredit owing to the too ardent* claims of enthusiasts Not only was this form of treatment not a cure-all, but in the great majority of cases it was essentially auxiliary to other methods

Dr H M GALT showed microscopical slides of parasites

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF OBSTETRICS

A MEETING of this Section was held on March 11th, Dr D G MADILL, the President, in the chair

Dr LOUIS CASSIDY described three cases of

HYPEREMESIS GRAVIDARUM

Vomiting in pregnancy, he said, must be differentiated both (1) from gastro-intestinal affections, uræmia, tumours of the brain or spinal cord, meningitis, and latent pyelitis, and (2) from other toxæmias of pregnancy—e g, pre-eclampsia. The term must be reserved for cases in which vomiting and pregnancy were synchronous and in which no cause other than pregnancy could account for the vomiting

Morning sickness, he had found, was more frequent in primiparæ than in multiparæ, and occurred between the 8th and 16th weeks It seemed to affect those carrying a male rather than those carrying a female child. After referring to Lindemann's post-mortem findings and the work of Miller on vagal control, Dr Cassidy drew attention to the psychical nature of some of the cases, remarking, however, that dogs and cats also suffer from vomiting in pregnancy Some authors (principally French) had pointed out that in hyperemesis there was deficiency in the corpus luteum, which was supposed to counteract the toxins generated by the chorionic villi According to Pinard, the occurrence of hyperemesis in conjunction with vesicular mole was as high as 19 in 27 cases In the hands of Seitz, van den Bergh's test showed an increase of bilirubin in the blood in hyperemesis over and above the normal increase during pregnancy

In cases of neurotic or reflex origin, said Dr Cassidy, the symptoms were intense thirst, bodily weakness, and emaciation, although distressing to the patient, they gave no real cause for alarm, and disappeared as pregnancy advanced In the toxic variety, on the other hand, the pulse-rate was increased in spite of rest in bed, the tongue was furred and dry, the skin was dry, and the urine, diminished in amount, contained pathological elements such as albumin, casts, and acetone Coma, delirium, and insomnia might occur and the condition was very grave The following were three cases recently treated successfully on different lines —

CASE 1 —A woman, aged 29, nine weeks pregnant, was admitted to hospital in an emaciated condition, vomiting constantly Her blood count was very fair, her blood pressure normal, but her urine, though normal in quantity, contained some albumin and casts She showed little response to treatment by rest in bed, starvation, lavage of the bowel, and purgation Corpus luteum was given in 1 c cm doses hypodermically, with little or no result The patient admitted that both she and her husband were anxious not to have a child at the time

Following the practice of Malinin of the Frauenklinik in Saratow, about 25 c cm of the patient's own blood was withdrawn from the median basilic vein and was reinjected in six different places This treatment was twice repeated at intervals of three days The patient began to improve rapidly The local parish priest visited the patient at this time, and it must remain undecided whether the Church or Medicine was responsible for the successful issue

Case 2 —Mrs B , aged 28, had been married four years, and was seven weeks pregnant She had had one full-term pregnancy two years before On admission her general condition was very bad She showed great fatigue and anæmia , her blood pressure was 110-80, and her pulse-rate 90 , the urine was scanty and contained albumin, casts, and acetone , the skin was dry , the tongue was dry and furred with sordes around lips and she suffered from great thirst

The uterus, which was retroverted, was replaced and a pessary inserted For the rest the treatment consisted of complete rest, purgation, lavage of the bowel, and rectal administration of sod bicarb and pot brom Corpus luteum extract proved ineffectual After about two weeks the patient began to improve and eventually she was discharged cured

Case 3—A primipara, aged 21, was 8 weeks pregnant The uterus was in the normal position, the pulse-rate was 84, there was slight anæmia, and the urine was scanty, containing albumin, casts, and large quantities of acetone The patient vomited on making the slightest movement in bed The usual treatment of purgation, lavage of the bowel, and administration of sod bicarb per rectum was given Corpus luteum had no effect given hypodermically Irradiation of the hypophysis was attempted

The first signs of improvement were noticed about 14 days after admission to the nursing home and followed rectal administration of pot brom gr 30 in four ounces of water morning and evening

Discussion

The President referred to a previous discussion on hyperemesis in early pregnancy,[1] and to the great stress then laid by Dr FitzGibbon on the neurotic element and its treatment by psychotherapy He personally thought that a great many of these cases were toxic in origin He had administered thyroid extract in a couple of cases, but had not found it of any value Dr Cassidy was to be congratulated on not having had to induce therapeutic abortion in any of his cases It was always taught that if starvation, thorough elimination, and rectal enemata did not stop the vomiting in these cases, then pregnancy should be stopped , yet Dr Cassidy's three cases had all been treated in different ways, and it had not been necessary to stop pregnancy in any of them

Dr Bethel Solomons said that if women were unaware that vomiting occurred in pregnancy few would suffer from it Patients were often in doubt as to their condition because they did not vomit, although told by their friends that they ought to do so He was a firm believer in the neurotic or psychological element as an ætiological factor, both in the mild and severe forms of vomiting Irrigation of the stomach had a good effect in all cases When done gently it caused no shock, and it had the excellent effect of (1) removing the backflow from the liver, and (2) clearing up hysterical cases because it was unpleasant It was also useful because purgatives could be left in the stomach, and he was surprised that Dr Cassidy had not adopted so simple and excellent a form of treatment in any of his cases He believed, too, in removing such things as basins from the patient's bedside, and in putting the patient on a full diet free from all greases While holding the view that most cases were of the psychological type, he had full knowledge that there were some few which were toxæmic and must be treated as such In the treatment by subcutaneous injection of the patient's own blood, it was interesting to note that the sequence of events had been injection of blood —marked *fright*—cure It was seldom necessary, he thought, to perform therapeutic abortion

Dr Gibbon FitzGibbon thought that the psychical element in these cases was very strong Patients got into the habit of vomiting, and thought that they should vomit While master of the Rotunda Hospital he had found that cases generally responded to starvation, elimination, and enemata, and he had only had to induce abortion twice One of these had died even after abortion These cases seemed to him to respond to all sorts of treatment, and the more he saw of them the more he was convinced of the psychical element in them He thought there was no reason to believe in the toxic element in hyperemesis Vomiting was always more severe in the multipara than the primipara In one case he had tried injecting human blood into the patient, but without any result There was far too much fear of letting these patients carry on, and he thought that pregnancy should be allowed to continue up to the fourteenth or sixteenth week, different methods of treatment being tried till then, before abortion was induced

Dr D Cannon asked if any effort had been made by gynæcologists to visualise the mechanism of the stomach in hyperemesis He had seen two cases in which it had been proved that achlorhydria was present He referred to work done by Prof D P D Wilkie in this connexion, and also to that of a German investigator who had shown that over-regurgitation of bile into the stomach would cause morning vomiting and other symptoms in pregnancy, and had suggested the administration of atropine sulphate Dr Cannon felt that these cases were functional and not toxic He wondered how a retroverted uterus could cause gastric symptoms, and yet he had often found that simple correction of the uterus did effect a cure An American observer had proved that duodenal stasis was present in hyperemesis

Dr G Tierney said that it was difficult to decide which cases were toxic in origin and which were not He considered that a number of them had a psychic as well as a toxic element He mentioned a paper recently published by Dr W E Levy, of New Orleans, in which it was stated as evidence of toxæmia that acetone was found in the urine, with diminution in the blood-sugar and in the CO_2-combining power of the blood The paper reported six cases in or about the fourth month of pregnancy They had been treated for a time on general lines without success before coming under his care Then they had been treated with insulin and glucose One woman, who was four months pregnant, and had been vomiting continuously for three weeks, was in such a state that he thought he would have to resort to therapeutic abortion, but after intravenous injection of insulin and of a 10 per cent solution of glucose, the vomiting had ceased, so that the patient went on to full term

Dr E Harvey suggested that the cases which were helped by insulin were those in which acidosis had been the cause of the vomiting Insulin would not necessarily be effective in other cases in which acidosis was not the cause of the vomiting

Dr Cassidy, in reply, said that he did not think the psychical effect of washing out the stomach would be sufficient to justify the distress which it would cause to these patients Most of them were of a neurotic type Generally, vomiting developed about the eighth week and stopped about the sixteenth week , it seemed that the vomiting diminished as the resisting powers of the body increased Acetone would be found in the urine in any case of starvation and should not be taken as pathognomonic of hyperemesis gravidarum An increase of bilirubin in the serum was, he thought, a sign that the case might be toxic From the clinical point of view it seemed that the important thing was to try to distinguish between the toxæmic and the purely neurotic case

Dr D Cannon read notes on a case of retroperitoneal fibroid, and a discussion followed

Reviews and Notices of Books.

EPIDEMIC DISEASES OF THE CENTRAL NERVOUS SYSTEM.

By ARTHUR SALUSBURY MACNALTY, M.A., M.D. Oxf. London: Faber and Gwyer, Ltd. 1927. Pp. 194. 12s. 6d.

THIS book is an expansion of the Milroy lectures for 1925. In publishing them in handy form Dr. MacNalty has done a real service, not only to those who specialise in epidemiology or in neurology, but to every member of the medical profession who wants to find out where we stand to-day in our knowledge of these comparatively modern types of epidemic disease. As the author says, "the increasing incidence of these diseases in Europe and America and the fact that they bring in their train new problems which concern the epidemiologist, the medical officer of health, the practising physician, and the public health administrator, demand that available information on the subject shall be collated and examined from all possible points of view." These words epitomise exactly Dr. MacNalty's book. It gives a concise account of the most important facts bearing on the subject with which it deals, and has the advantage of being written by one who, from his wide experience and ripe judgment, is able to present them in a balanced and assimilable form.

The three diseases here considered are cerebro-spinal fever, acute poliomyelitis, and encephalitis lethargica (epidemic encephalitis). These are compared and contrasted from various, but, in each case, from similar, points of view. The book is conveniently divided into six parts. After a short introduction Part I. deals with the increasing susceptibility of the central nervous system to attacks of epidemic disease. Various theories attempting to explain this are discussed and considered; thus the theory of increased facilities for spread, the occurrence of epidemic cycles or waves, and also the epidemic "constitution," a term which, as the author says, "is admittedly vague." Whilst paying adequate consideration to each of these the author puts forwards the suggestion that, possibly, it may in the future prove more fruitful to give "the soil" at least equal consideration with "the seed." In this connexion he refers to the striking fact, which cannot be overlooked, that the earliest appearance in epidemic form of the present wave of encephalitis lethargica coincided in time with the peak (or should we say the beginning of the plateau) of distress due to war—it was the winter, 1916–17—whilst it coincided in place with the area in which that distress occurred in its greatest intensity—viz., Central Europe. If this was merely a coincidence it was a remarkable one. The question as to whether the human nervous system is becoming more susceptible owing to the rush and strain of modern life—a very real possibility—is discussed, and the suggestion is tentatively put forward that we may be dealing with organisms which, if not new, are at least changing their pathogenic propensities.

After an interesting survey of the evidence as to the possibility of these diseases being transmitted from domestic animals the author finds it "not proven." Part II. relates the steps by which the epidemic nature of diseases of the central nervous system has gradually been recognised. The chapters in this section deserve careful study, for although these diseases are officially notifiable as infectious, yet in practice their mode of spread is so obscure and the actual danger of direct infection seems so slight that it is sometimes difficult to persuade doctor or patient that serious precautions are necessary. In reading Dr. MacNalty's reasoned and convincing account it should be remembered that the author himself has played no small part in helping to lay the foundations upon which our present knowledge of such infectivity is being built. Parts III., IV., and V. deal with the history and epidemiology of each of the three diseases in turn and are full of information presented in attractive form. In the concluding chapters (Part VI.) the means at present available for preventing the spread of these epidemic diseases are discussed. Stress is laid on the importance of recognising "abortive cases," which probably play an important part in the spread of all three diseases. The necessity of treating each individual case as a potential source of infection is duly emphasised, both as regards personal isolation, disinfection of the patient, and his surroundings. Unfortunately, our knowledge is still slender as to the duration of such infection, hence the difficulty in laying down any definite rules as to how long these precautions should be continued.

In his conclusion Dr. MacNalty points out that, although an alarming increase in epidemic nervous diseases is shown by the notification returns, the actual increase is probably considerably greater. This is certainly true in the case of encephalitis lethargica. So long as medical practitioners are content to dismiss as "influenza" every slight febrile attack which they meet with, although the data for such a diagnosis may be quite inadequate, so long will our official statistics remain far from true estimates.

An additional recommendation of these lectures is the charming style in which they are written.

HUMAN PATHOLOGY:

A Text-book by HOWARD T. KARSNER, M.D., Professor of Pathology, School of Medicine, Western Reserve University, Cleveland, Ohio. With an introduction by SIMON FLEXNER, M.D. London and Philadelphia: J. B. Lippincott Company. 1926. With 20 illustrations in colour and 443 black and white. Pp. 980. 45s.

IN this text-book Prof. Karsner proceeds along conventional lines in the presentation and treatment of his subject. The book is divided into two parts. The first deals with general pathology, the retrogressive changes, disturbances of circulation, inflammation and infection, the progressive changes and tumours being included in this part. Part II. is devoted to systemic pathology, and in the several chapters the diseases of the various systems and organs are discussed. A table or synopsis of the contents is given at the beginning of each chapter in the section of general pathology, a feature on which the author in his preface lays some stress, and at the end of every chapter is a well selected list of references which, while making no pretention to completeness, will admirably serve to direct the student in his more detailed reading. There are numerous illustrations, both photographs and drawings; many of them, we are told, were made under the direction of Dr. Simon Flexner for a book which he himself intended to write. They are clear and well produced and successfully fulfil their purpose of clarifying the text. The book is well printed and there is a good index.

Prof. Karsner's text-book is a notable addition to pathological literature; the teaching is sound and orthodox, and the subject is treated in the widest sense. The amount of information contained between its covers is remarkable, and debatable points are fairly and adequately discussed. If we have a criticism it is that the student may find it occasionally rather tough reading. The author has not attempted a smooth dogmatic account of his subject, but wherever any doubt exists he mentions the views and observations of different workers. The result is occasionally a rather jerky unconnected description loaded with detail, and the inexperienced reader may feel the lack of a definite lead. It might be replied, however, and with perfect justice, that pathology has passed the stage of smooth dogmatism, and that the student must learn to think for himself. We believe this to be so, and that Prof. Karsner's book will enjoy the popularity that it merits.

DISEASES OF THE NOSE AND THROAT

Third edition By Sir STCLAIR THOMSON, M D, F R C P, F.R C S, Consulting Surgeon for Diseases of the Throat, King's College Hospital London Cassell and Company 1926 Pp 943 45s

THE third edition of this excellent work remains substantially the same as its predecessors New sections have been written on some rare conditions, such as chorditis fibrinosa and dermoid polypi of the nasopharynx The articles on a few subjects which have recently been prominent, such as œsophagectasia, ozæna and cocaine substitutes, have been rewritten or rearranged It is in the sections on operative treatment that the principal alterations are to be found The operation of tonsillotomy is very properly omitted, the method of laryngectomy from above downwards takes the place of excision from below, and lateral pharyngotomy is described in full detail New illustrations have been given where required in explanation of the new matter It need only be added that the very high standard set by Sir StClair Thomson in the earlier editions has been fully maintained in the present volume, which is one of the best and most complete books on its subject in the English language

---

LIPOID TREATMENT OF TUBERCULOSIS.

Das Problem der Tuberkulose Behandlung mit Fettstoffen By FERDINAND MATTAUSCH Berlin and Vienna Urban and Schwarzenberg 1926 Pp 66 M 2 40

APPROXIMATELY half of this small monograph is devoted to a clinical inquiry into the treatment of various forms of tuberculosis with a non-specific lipoid known as gamelan or lipomykol with which encouraging results were obtained The rest of the work is a very brief summary of some aspects of the biochemistry of the fats and lipoids in tuberculosis This summary is by no means exhaustive, the excellent text-book on the Chemistry of Tuberculosis by Gideon Wells, L M De Witt, and E R Long published in 1923 seems to have escaped the author's notice The various fatty substances extracted from the tubercle bacillus, the lipoids in tuberculous tissues and cellular and humoral resistance in relation to the lipoids are described briefly The reader is spared whole pages of graphic formulæ, which too often loom disproportionately large in monographs of this kind, and technical laboratory details are almost entirely in the background The bibliography is, on the whole, good considering the amount of work annually put forth on this subject Too much space is devoted to gamelan, of which the exact formula is not given, and too little to the broader aspects of the subject to make the book a well-balanced summary

---

NATIONALITY

The Racial Basis of Civilisation By F H HANKINS, Professor of Sociology in Smith College, New York London and New York A A Knopf 1926 Pp 384 14s

DOCTRINES of racial superiority have always existed among this or that chosen people, in recent times their rôle has been much exalted Aryanism is the original source from which have been derived teutonism in Germany, celtism in France, and anglo-saxonism in England and America, and these cults have been pursued partly by serious scholars and more often by patriots and partisans, until each nation is convinced of its inherent superiority and the grandeur of its destiny. Prof Hankins sets to work to pull these doctrines to pieces, and this he does in a bright and interesting way and with a success of which his readers must judge for themselves English, French, and Germans are mixtures in varying proportions of the same components Nordics, Alpines, and Mediterraneans are everywhere in Western Europe Nationality is the precursor rather than the result of race, which is a unity created by social development and similarity of intellectual factors which lead to unity of blood The "English race" is a cultural, not a zoological unit The essential thing which gives any nation a just position of superiority in the world is that it should be the product of a crossing of able stocks—a combination, for example, of the aggressive adventurous Nordic with the reflective artistic Mediterranean This gives a greater range of variation and a higher probability of getting more of those biological accidents which we call geniuses It gives, too, a better chance of finding new lines of cultural development which soon amalgamate the hybrids into a good sociological species Such in brief is the author's chief thesis He puts it forcibly, and there is probably more to be said on the other side than he allows, but he is thoroughly interesting all the time The book is beautifully produced

---

SYMBIONTICISM AND THE ORIGIN OF SPECIES

By I E WALLIN, Sc D Professor of Anatomy in the University of Colorado School of Medicine London Baillière, Tindall and Cox 1927 Pp 171 13s 6d

THERE are, says Prof Wallin, two views of the nature of the mitochondria which have engaged the attention of almost every respectable cytologist in recent years One is that they are cell organs the other that they are symbiotic micro-organisms He does not mention the third—that they are artefacts He has convinced himself that the second view is correct Morphologically they are like micro-organisms, and in cultures he has obtained minute bodies of a tolerably similar appearance The evidence is not conclusive It is conceivable for example that parts of cells may be cultivated in vitro as well as whole cells, the viruses which cannot multiply apart from cells may obviously be of this nature It is indeed, difficult to see how convincing proof of the organismal nature of mitochondria could be obtained, for in the last resort one would come to the insoluble problem of what exactly an organism is and whether things exist *which are partly organisms* However, taking the nature of mitochondria as settled, Prof Wallin goes further than those who have upheld his view before for he claims that this general symbiosis plays a fundamental rôle in the evolution of new species His book is readable and interesting, and there is a useful bibliography The speculations include a body of facts which need careful consideration, his interpretation of them may turn out to be correct

---

THE POSITION OF SCIENCE

Gallio or the Tyranny of Science By J W N SULLIVAN London Kegan Paul, Trench, Trubner and Co 1927 Pp 96 2s 6d

THE booklets of the "To-day and to-morrow" series vary a great deal in quality, this is one of the best which we have seen It puts the difficulties into which physical science has landed itself by its exuberant progress with point and wit, and with as much clarity as the present apparent impasse will allow The Victorian "scientist" was essentially a mechanician and it seemed clear to him that the mathematical statement of the world which he was elaborating must in the end prove complete and satisfactory as a summary of the facts if not as an explanation of them The philosopher who is now advancing at the edge of such apprehension as is possible to the favoured few realises that the world is not a fact but an evolutionary process in which the separation of mind from matter and of mind from mind must be regarded as unreal According to the author, the concrete facts of experience are better expressed by the artist or the poet than by the physicist, the authentic tidings of invisible things have been distorted in their scientific analysis It is all very interesting and stimulating and very difficult to understand One feels envious of the next generation or the next but one to whom the spirituality of mathematical physics will be plain sailing

JOURNALS

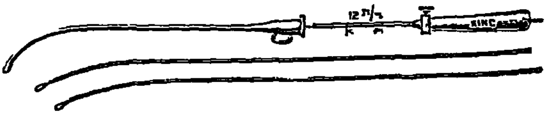
British Journal of Children's Diseases Vol XXIV January–March —Dr J D Rolleston contributes a paper on recent advances in the ætiology, diagnosis, prophylaxis, and treatment of the acute exanthemata, his conclusions being as follows · (1) The *Streptococcus hæmolyticus scarlatinæ*, described by the Dicks, has more claim than any other organism to be regarded as the causal agent of scarlet fever (2) Active immunisation against scarlet fever by injection of scarlatinal toxin is still in the experimental stage, but is full of promise (3) The use of a concentrated scarlet fever antitoxin deserves trial from an early stage in all severe cases (4) The diplococcus described by Tunnicliff is more likely to be the causal organism of measles than any other hitherto described (5) The prophylaxis of measles by injection of convalescent serum is of great value in affording temporary protection from an attack or in diminishing its severity if it occurs, and is specially indicated in ill-nourished children under the age of five living in unhygienic surroundings (6) Active immunisation against measles which offers a more permanent protection against the disease is still in the experimental stage (7) There is no justification for regarding alastrim as ætiologically distinct from small-pox (8) Herpes febrilis and herpes zoster, though closely related are ætiologically distinct from one another —In a paper entitled Petit Mal or Cardiac Disturbance Dr G A. Sutherland, who records two illustrative cases, remarks that, in connexion with attacks suggestive of petit mal tachycardia may be present without other obvious cardiac changes The symptoms of an attack are present only during the period of paroxysmal tachycardia and usually accompany the onset of the new cardiac rhythm An attack is often definitely induced by excitement or bodily exertion While an organic basis of disease in the heart may be present, a similar condition of paroxysmal tachycardia may occur in hearts organically sound —In a paper on Microcephaly Dr T Brushfield and Dr W Wyatt describe the pathological changes in ten cases of true microcephaly observed at the Fountain Mental Hospital They point out that whereas all the cases during life were more or less alike, the pathological lesions differed considerably Whatever the lesion in the cerebral hemisphere the result was the same—viz , destruction of the upper neurons of the pyramidal tract The unantagonised influences from the extrapyramidal tracts and probably from the cerebellum also, which is usually well-developed, explains the clinical features of paresis and rigidity — Dr R Richards contributes a paper on bacillary dysentery in Aberdeen, his conclusions being as follows (1) The occurrence of true bacillary dysentery among the general population is not so uncommon as is usually stated (2) Treatment by magnesium sulphate is almost specific for bacillary dysentery The diet is almost equally important No food or liquid which leaves a residue is permissible (3) Apart from bacteriological examination the following points are of diagnostic assistance (*a*) the macroscopic appearance of the stool, which is like scraps of flesh in raw meat juice , (*b*) the microscopic appearance of the stool, a smear of the fæces showing abundance of polymorphonuclear leucocytes Many "ghost" cells and macrophages —The abstracts from current literature are devoted to tuberculosis

Chinese Journal of Physiology —The Chinese Physiological Society, the headquarters of which is at the Pekin Union Medical College, is composed of native and foreign physiologists, biochemists, and pharmacologists, and its members have long felt the need of a publication to stimulate scientific research in that backward country They have, therefore, with admirable courage, launched this quarterly journal as a symbol of the desire of the Chinese to help themselves, and to do so in " the spirit of international goodwill and cooperation manifested by all men of science " The journal is printed in English, as the language most practically useful to the bulk of the physiological world The first number contains articles on the effect of starvation on the intestinal epithelium of the albino mouse, the aconite of Hunan, which has properties comparable with the European varieties , bastard anise poisoning, ephedrine anæsthesia mixtures, the proteolytic ferment of *Cucumis melo*, a Chinese cantaloupe, a method of anastomosing vessels with aluminium couplers studies on the denaturation of proteins, and other original contributions of merit The assumption by a Chinese society of national responsibility for contributing to the scientific progress of the world is welcome

New Inventions.

A EUSTACHIAN SOUND

Success in the treatment of middle-ear deafness depends upon a correct Eustachian catheter technique, and inflation of the tympanum and dilatation and medication of the tube have alone survived the test of experience Most aurists have devised some appliance to this end, or favour some modification or elaboration of technique which has been of help to them in practice The accompanying illustration of my own small contribution to the matter represents a graduated carrier and a set of flexible Eustachian sounds of stainless steel. The carrier consists of a convenient handle and a stem The latter measures just 36 mm , the length of the adult Eustachian tube, and is divided into three sections of 12 mm each by marks which inform the operator of the depth to which the sound has penetrated the tube When introduced into the catheter as far as the second division (24 mm) the bulbous end of the sound is at the isthmus tubæ, a common site of stricture , when the third and last division is reached, the tip of the sound should have passed the tympanic ostium They cannot replace the indispensable gum elastic bougies of Hunter Tod, nor are they intended to do so, for it is obvious that in the case of a tortuous Eustachian tube they would be both useless and dangerous But in a straight tube they will pass an obstruction before which the gum elastic bougie bends back and reappears in the pharynx They have made it possible to introduce a Weber Leil's inner catheter beyond an obstruction otherwise impassable, and in one case of Ménière's symptom-complex with Eustachian obstruction they have given relief where other methods have failed The graduated carrier also enables a roughened wire armed with a cotton-wool tip impregnated with solution of silver nitrate or other medicament to be introduced for a known distance into the tube Atropine ointment so applied will relieve some cases of tinnitus, even when otosclerosis is the cause The sounds can be sterilised by boiling, but cannot break and leave a piece impacted in the Eustachian tube, as the ordinary celluloid sounds have been known to do There is little originality in this application of well-known principles to a special purpose, but the work for which it is devised is very difficult, and every little helps



The appliance is made by Messrs A Charles King, Ltd , 34, Devonshire-street, London, W 1

EVIDENCE AND RUMOUR

Dr Bernard Hart s recently published book on Psychopathology "[1] is an expansion of his Goulsman lectures, which were fully reported in our lumns at the time of their delivery [2] An added say on the "Psychology of Rumour," originally itten during the war, now brings before a wider blic an analysis of a form of behaviour that involves r activities more intimately, perhaps, than intellectual pride will readily accept Rumour depends only upon accuracy of transmission, but primarily on the accuracy of the report of the first individual the series concerned in its transmission, and Dr rt accordingly begins with an examination of psychology of evidence Historians seem to have the first to investigate the reliability of evidence, formerly they did as many of us do now, they pted the moral character of a writer as the test his reliability Now, however, whilst moral acter remains important, they take into account y possible condition which may have exerted an ence upon the particular statement under examina-, the source of the witness's knowledge, the interval separating him from the events in tion, his views and prejudices, his profession, ion, and political party They consider, moreover, only whether the witness is deliberately lying, but ther and how far he is unconsciously perverting truth owing to the factors just mentioned On psychological side Stern, of Breslau, carried out ainstaking research and by actual experiment t in the most complete and definite manner two ly held views, that evidence given with the best wledge and honesty is a correct reproduction of ality, and that evidence which is shown to be must be due to deliberate lying, or at least to able carelessness In addition, though detail and racy are both diminished by lapse of time, the ess's belief in the truth of his evidence is little ted Legal writers have noted the effect of estive questions of discussion subsequent to the t, of prior knowledge and interests, and the ulses to assign satisfying motives and to round story

the factors noted above Dr Hart applies in conceptions employed in modern psychology word "complex" has now passed into common h, and if its meaning and full implications were rstood with conviction man's attitude to man d be radically changed A complex is a system eas with a certain affective load, or emotional e, which tends to produce trains of thought ng in a definite direction, and the complex may its action without the individual himself being least aware that his thinking is so directed An erroneous belief thus formed is given a superficial plausibility by a process of self-deception termed "rationalisation" The statement that the conduct and thought of an individual are mainly directed by reason is opposed to the teaching of modern psychology, much of the thinking which we imagine to be rational is in reality the result of non-conscious complexes, and the reasons with which we support it are not its basis but secondary products—rationalisations—that serve to hide irrational origin Even the first stage of memory—perception—is influenced by endogenous factors, complexes exercise a selective action upon it, we see what we are interested in seeing what we expect to see, and are unaware of our interest or our expectation In the second factor—conservation—perversion may be produced by simple forgetting and by active forgetting or repression, whereby elements may be essentially altered in their character The third process—reproduction—is influenced by suggestive questions, or by the witness being in the centre of the stage, when the grandiose or "self-assertion" group of complexes comes into action, here arises the impulse to say something effective, to round off the story and fill in the gaps. When he discusses rumour Dr Hart disagrees with those writers who see in crowds intrinsically different mechanisms from those exhibited by their members in isolation Both Le Bon and Conway assume that the conduct and thought of the individual are mainly directed by reason whilst emotional behaviour marks the crowd, but the difference is only one of degree. Herd instinct is one of the cardinal factors responsible for the non-rational type of thought and determines the major part of our individual belief and rules of conduct Genuine rational thinking constitutes but a small part of our mental activities, and in a crowd even this small part may be abrogated so that non-rational thinking becomes more obvious and unrestrained In war-time rumour there is a probability that widespread and fundamental complexes determined its generic types Stories of atrocities satisfy one such complex, and the industrious propagation and general acceptance of the report of an enormous increase in the illegitimate birth-rate seem to have owed their existence to phantasies of an obviously sexual origin But the influence of herd instinct is such that, when maximally stimulated, "its action overwhelmingly dominates the mind, non-rational opinions are disseminated with prodigious ease, and the rational activities, with their capacities for cool criticism, are at a low ebb"

Though written with special reference to a time of war, these last observations can find application in other cases of strife between nations or communities. Except in their form they contain little that has not been enunciated by philosophers of all periods, and that they remain true throughout the ages is a testimony to the strength of the instinctive and emotional forces that influence human conduct

THE RETAINED TESTICLE

The imperfectly descended testicle, the mechanism of its descent, its pathology and its treatment are of perennial interest to the surgeon, and the Hunterian lecture by Prof A H Southam and Miss E R A Cooper, which we publish this week, will be welcomed as an important addition to our knowledge It is pointed out as a remarkable fact that but little light has been thrown on the subject since the days of John Hunter Possibly this is because the accuracy of his observations and the soundness of his inferences established the main anatomical facts and left only details and special points to be elucidated by subsequent observers ASTLEY COOPER, in his monograph published in 1830 on "The Structure and Diseases of the Testis" gave an account of the descent of the testis and the anatomy of the imperfect organ, but remained silent as to its physiology and pathology It is because of their bearing on these two last problems that the investigations recorded in the present Hunterian lecture are especially valuable

It is generally recognised that usually, but not always, an imperfectly descended testicle in an adult is functionless as regards spermatogenesis, though it is generally (but again not always) able to produce the secretion necessary for the development of secondary male characteristics The reason why spermatogenesis is absent has been the subject of discussion and even of controversy Two views have been held to explain it The first is that the failure of function is due to some inherent primary developmental defect, the second is that for the final stages of normal development it is essential for the testis to occupy its correct position in the scrotum To explain this effect of position it has been suggested that the lower temperature of the scrotum is the essential factor for spermatogenesis, and also that in the scrotum the gland is relieved from the pressure exerted by the diaphragm The question is important because the answer must obviously influence treatment If the loss is due to some essential developmental abnormality of the genital gland, the operation of orchidopexy will do nothing to assist the performance of its chief function, whereas if the arrest is due to secondary causes associated with its retained position the surgeon will feel that orchidopexy may not only give a good anatomical result but also—provided it is performed before puberty—promote satisfactory physiological development To solve the problem Mr SOUTHAM and Dr COOPER have compared the macroscopical and microscopical condition of retained testicles with those normally descended in boys of similar ages, and have come to the conclusion that the changes seen in the testicles of adult cryptorchids are secondary They believe that the retained testis develops normally during early postnatal life, but later undergoes retrogressive changes if it has not reached the scrotum Other important conclusions are that the younger the age at which a retained testicle is examined the more nearly does it approach normal structure, and that the further the testicle has descended in pre-adolescent life the more nearly does its structure resemble that of a scrotal gland of the same age The descent of the testicles should be complete, and both should lie in the scrotum by the end of fœtal life, but there is no doubt that spontaneous descent may take place some time after birth The present investigation indicates that it may occur until the child is three years old, but it is extremely improbable after that age Cases have been recorded in which descent is said to have been completed at puberty or even later, but fully authenticated examples of this are very rare, a source of error being extreme retraction of a properly descended gland

It may be concluded that if the functional activity of the testis depends upon its scrotal position during the final stages of development, then its normal anatomical and physiological evolution may be completed if it be placed in the scrotum before secondary changes occur The *latest age for the* operation should be about 12 years, the earliest is some time after the third year, up to which time spontaneous descent is still possible About the age of six years may be taken as a desirable early limit Besides the restoration of function there are other factors which strongly indicate operation In the great majority of cases, even when there is no obvious hernia, there is a patent funicular process or potential hernia The retained testis is also liable after puberty to attacks of disabling pain, possibly due to slight injury or to attacks of inflammation, not to mention the alleged increased liability of the imperfectly descended organ to malignant disease A further important reason for operation is that in many occupations and professions, including the public services, a retained testicle will be a bar to admission As operative procedures, the following are possible orchidopexy, or transference of the testicle to the scrotum, abdominal replacement, or return of the testicle to the abdominal cavity after the hernial sac has been removed, and excision of the misplaced gland Mr SOUTHAM and Dr COOPER conclude—and the great majority of surgeons will agree with them—that orchidopexy is the method of choice Abdominal replacement, though it has had some strong advocates, should not be performed except in exceptional cases, usually where the condition is bilateral, in which orchidopexy is impossible Functional development is extremely improbable when the testis is returned to the peritoneal cavity, and the dangers of the condition are not removed Excision is only very exceptionally indicated in children, though it may be called for in adults where there is one normal scrotal testicle Above all, it should never be done in bilateral cryptorchids unless there is some special indication such as malignant disease or torsion One additional point may be mentioned that is not touched on in the lecture That is, that after a successful orchidopexy growth and development take place not only in the testicle but also in the spermatic cord If the operation be performed in children between the ages of 6 and 12 it is unusual to find that the vas and vessels are too short to permit of transference to the scrotum The imperfectly descended testicle is often a very mobile structure, being sometimes palpable at the external ring or in the inguinal canal, whilst at another time it may be within the abdomen Hence in children it is often possible to transfer to the scrotum a testicle which is apparently abdominal in position After transference there will usually be some tautness about the cord, but in a few months, as the result of growth and development, the structures will probably be as free and lax as those on the sound side The conclusions which Mr SOUTHAM and Dr COOPER have reached are very encouraging They confirm many of the clinical observations that have been made, and put them, together with the operation of orchidopexy, on a sound and scientific basis

◆

THE POLLUTION OF RIVERS

WHILE the concerted drainage of towns has undoubtedly improved the public health, this improvement has too often been at the expense of the natural drainage channels of the country—its rivers The effects of river pollution are more apparent in a small, densely populated country, with small rivers, like England, than in continental countries with their larger river systems and more scattered populations Almost all our rivers, excepting only the Test and the Kennet, are in fact illegally polluted. A factor which, in England, has led to a relaxed public conscience in this matter is the low esteem in which fresh-water fish are held There is probably no place in England as much as a hundred miles from the sea, and sea fish are obtainable, when desired, everywhere

here It is not only the discharge of untreated or insufficiently treated sewage which has led to the foul condition of many rivers which once contained large supplies of fish. Industry has played a great part in pollution Apart from the advantage of establishing a works on a *navigable* river the proximity of any river, however small, provides water for washing, solution, and other such operations, as well as for steam raising and for cooling It also provides an easy and not too obvious means of getting rid of waste liquors, sludges, muds, pulps, and other by-products of industry The one-way movement of a non-tidal stream and the oscillatory motion of a tidal one, are means both of removing the matter discharged and of merging its identity with that of other pollutions in the stream itself.

The results of the unrestricted discharge of domestic and factory effluents are all too apparent Most organic pollution has the one direct result of making a great demand on the oxygen dissolved in water, often reducing it to less than what is a bare necessity for the maintenance of fish life Mr H W Harvey of the Marine Biological Laboratory at Plymouth has recently called attention in *Nature* to the positively toxic effect—apart from any question of de-aeration—of the products of putrefaction of some of the proteins present in effluents Many inorganic matters in factory effluents, such as acids, alkalis, lead salts (which have done much harm in Wales) are definitely poisonous to the smaller life of rivers on which fish feed as well as to fish themselves It is true, as we have recently taken occasion to point out,[1] that both old and recent Acts of Parliament provide some remedies for the present state of affairs which the many river surveys, conducted by or under the direction of the Ministry of Agriculture and Fisheries, show to be alarming, from the point of view of anglers, nature lovers, and those who consider streams of pure water a necessary feature of a healthy countryside It does not appear, however, in view of the delicate balance of duties, interests, local advantages, both in rating and employment, from unfettered industrial development, that much will be done by attempts to enforce rather feeble enactments Much can, nevertheless, be done, especially by members of the medical profession, to quicken the conscience of all concerned with rivers, sewage works and factories The Thames Conservancy Board is ever watchful and the Port of London Authority is understood to have special powers of its own The surveys above mentioned have aroused much local interest and medical officers have done good work in the matter The real difficulties attending the treatment of such discharges as those sent out in the winter from beet-sugar works are to be grappled with by the Director of Research on River Pollution who will be appointed within the next few weeks by the Department of Scientific and Industrial Research This officer will have a busy time, as apparently all such problems will be referred to him as they arise. As soon as solutions are found every effort must be made to apply them to actual cases of pollution

When those responsible for river pollution forego their plea of a prescriptive right to pollute, when they find that it is not a necessary result of industry or of "sanitation," that it makes them unpopular with their neighbours, and that all the profits of industry will not be absorbed in rendering its by-products inoffensive, or that sewage treatment should be a means of preventing river pollution, our streams will begin to improve Very little will be done until it is evident that a considerable proportion of the community desire some action There are many once beautiful, well-stocked streams in which now the angler cannot find fish, the boy may be poisoned if he bathes, and the oarsman must labour against more than fluid friction Even these streams could be improved, greatly to the public benefit, by tact, persuasion, and a hint as to legal obligations which might, in the last resort, have to be insisted on

Annotations.

"Ne quid nimis"

HOSPITAL ALMONERS

The small committee, which was later to become the Institute of Hospital Almoners first met in 1907, and it is a tribute to the foresight of its members that the work has steadily developed along the lines then laid down while it has also been found possible in the face of changing conditions, to adapt it without loss of continuity The formation of the Institute in 1922 as an Incorporated Society marked a definite step in the establishment of the movement and one that seemed in accordance with its growing importance A general survey of the work of the last 20 years is included in the annual report of the Institute for 1926 The first quarter of the twentieth century has shown an increase in social legislation which affects the details of an almoner's work in many ways Gradually the State has taken over certain types of social work which were carried through the experimental stages by voluntary agents In these schemes of cooperation with the State the almoner acts as an intermediary between the authorities and the hospital patient She ensures that no patient need go without available treatment through lack of knowledge and provides a directly human point of contact with an impersonal system

A perusal of the reports of the almoners' departments in the various hospitals gives some indication of the growth of the work The almoner helps hospital patients not merely to carry out prescribed treatment in the face of great difficulties, but is often able to help them to re-establish themselves after the dislocation consequent on illness or accident Another interesting feature is the growth of research work, carried out in cooperation with the medical staff In studies of encephalitis lethargica, rheumatism and cancer, for instance, the careful records kept by almoners of after-care and "follow-up" work provide valuable data In certain types of disease, too, the number of readmissions to hospital is appreciably lessened by systematic visiting of patients in their homes The financial aspect of the work has also a real interest and value The administrative expenses of the department are a comparatively small part of the general costs of the hospital, funds for the social work involved being in many hospitals almost entirely raised by appeals to outside agencies, employers and friends, and by contributions from the patients themselves Where however, special provision exists for the needs of the patients the work can be greatly extended For example, the Cicely Northcote Trust of St Thomas's Hospital enables the almoners to promote the welfare of past and present patients to an extent impossible to achieve when no extra funds are available The seventeenth annual report of the Northcote Trust is a record of solid achievement The report emphasises not only the social and economic value of the services rendered, but also the efforts made to obtain a right understanding of the patient's point of view. Last year, for example, the General Strike left its mark on all hospital social service, the Northcote Trust has to its credit during that week of confusion 97 transport journeys with patients, some of them as far away as Southampton and Brighton Of the ordinary doings of the year mention may be made of the insulin work, which affords a good instance of the new problems that face the social service departments year by year After a diabetic patient leaves the hospital ward the supply of insulin has to be maintained This may necessitate arrangements with the approved societies or with the guardians, but there are patients who do not fall into either category There is the patient who can afford to pay for his insulin, but in so doing cripples the family resources, especially when the cost of special diet is added Such a patient may now obtain insulin at cost price through the hospital dispensary That this particular piece of work is welcomed by patients and physicians at St Thomas s is made clear by the chart contained in the report Here is shown a steady increase in the supply of insulin since the beginning of 1925, culminating in a monthly distribution of nearly half a million units in September 1926

---

[1] The Lancet, 1926, ii, 714

This is the aspect of the almoners' work which is likely to make most appeal to the public but her sterner duties include the prevention of abuse of hospitals by patients who could afford to pay a private doctor or who are entitled to the services of a panel practitioner and do not require special hospital treatment In order to ensure that candidates for almonerships are fit for these two-fold responsibilities, the Institute of Hospital Almoners insists on a high standard of education and personality in its students Of 42 applicants interviewed last year only 30 were admitted The course of training covers a period of two years, of which four months are spent in the offices of a Charity Organisation Society during nine months under the direction of the London School of Economics, physiology, economics, social legislation and administration are studied, after which 11 months' practical work at a hospital under the direction of an almoner completes the course In 1926 15 appointments of almoners trained by the Institute are reported Practitioners who are consulted as to a profession by educated women between the ages of 20 and 35 may note that the work will be congenial to many women, while 40 guineas is not a heavy training fee for a profession of growing importance of which the remuneration usually starts at £200, the larger hospitals paying £350 or more to their head almoner

CONTAGIOUS ABORTION AND MALTA FEVER IN ENGLAND

THE discovery by A E Evans in 1918 that *Bacillus (Brucella) abortus* of Bang, the organism of contagious abortion in cattle, could hardly be distinguished from *Brucella melitensis*, the cause of Malta fever in man, has turned out to be something more than a bacteriological curiosity Once people began to look for them, examples of human infection with *abortus* were soon found Cases of obscure pyrexia due to this organism were described in South Africa and in the last few years quite a number have been identified in the United States It was obviously only a question of time before the new disease was discovered wherever contagious abortion occurs, which is everywhere that cattle are kept Last year Dr G S Wilson and Miss M Nutt showed that the organism was quite common in the milk supplied in Manchester and now Dr J Bamforth, in a note published on page 818 of this issue, describes two human cases in or near London The remarkable thing is that obvious human infection should be so rare This is quite likely due to the fact that those who drink raw milk are certain to take in small doses of the bacilli and in this way to become immunised without ever having a definite febrile attack, it is known that *abortus* agglutinins are by no means uncommon in the blood of children examined at random If this is the explanation, the absence of a similar immunisation to *melitensis* in the Mediterranean area needs examination, goats infected with Malta fever probably excrete larger quantities of bacilli The two infections have been shown to immunise against one another, hence the proposal to protect man against Malta fever with *abortus* vaccination, which may prove useful when it has been tried on an adequate scale Hence, too, the farmers' custom, widespread in Britain, of running a billy-goat with a herd of cows as a preventive of abortion In old days, before we were protected by a paternal Board of Agriculture, all the goats in Western Europe were no doubt more or less infected with Malta fever, and our ancestors seem to have found out empirically that small doses of *melitensis* scattered about among their herds by contact with goats were to some extent a protection against the loss of calves which was and still is a very serious matter to the cow-breeder How far *abortus* fever may correctly be called a "new" disease is largely a question of terminology If their pathogenic relationships to animals were not so distinct, *abortus* and *melitensis* would be called varieties of a single species and indeed they are at least as nearly akin as the various forms of, for example, diphtheria and tetanus bacilli, all of which give rise to diseases which as far as we know are identical Similarly apart from their pathogenic action it is difficult to distinguish the bacillus of pseudo-tuberculosis in guinea pigs from the plague bacillus The facts raise many fundamental problems for the systematists epidemiologists, and philosophers Practically in the present instance there does seem to be some difference *abortus* infection is generally milder than Malta fever —so mild perhaps it often escapes notice Moreover, as Dr. Bamforth has shown, it cannot be avoided by living in England where one is fairly safe from the real Malta fever

BACTERIOLOGY OF HERPES

IN a recent number of the *U S Public Health Reports* (1927, xlii, 171) Alice Evans records the result of investigations with six herpes and so called encephalitis viruses obtained from different workers Four of these strains were herpetic viruses obtained from human vesicles The fifth was the Beckley strain isolated by Flexner, and the sixth was obtained from the brain of a case of acute encephalitis lethargica by Perdrau From all six samples of virus, either from the glycerinated brain as received from the sender or from the brains of inoculated rabbits streptococci could be isolated by planting a thick emulsion of infected brain tissue in a cooked meat medium In some instances masses of cocci could be demonstrated in smears of brain substance stained by Gram's method Berkefeld filtrates of these brain emulsions heavily inoculated into meat medium also gave rise to cultures of streptococci A culture from one of the cases inoculated into rabbits produced nervous symptoms In addition to the streptococcus (details of the biology of which are not given in the article), the author also cultivated spore-producing rod-shaped organisms from all the strains of virus Details of these organisms, which may also be obtained from cultures of a Berkefeld filter, together with a description of the disease produced in experimental animals are promised in a forthcoming paper

TORSION OF THE SPERMATIC CORD

ACCORDING to Dr Meredith F Campbell,[1] who reports 15 cases seen in six years at the Bellevue Hospital, New York, the relatively few recorded examples of torsion of the spermatic cord are not a true index of the incidence of this lesion Only 120 cases were reported before 1920, since when 17 more have been published Undoubtedly many pass unrecognised under a diagnosis of epididymitis or orchitis and subside without an operation being necessary Moreover, many cases of unexplained gangrene of the testicle which come to operation have probably been due to torsion of the spermatic cord In practically all cases some form of congenital malformation has been found The chief predisposing cause is abnormal mobility of the testicle Nearly half the patients give a history of imperfectly descended testicle on the affected side Other anomalies include a spacious tunica vaginalis, elongation of the globus minor or abnormal attachment of the mesentery to the lower pole of the testis Sudden muscular effort or violent straining is the most frequent immediate antecedent of the condition Three-fourths of those affected are young adults but torsion of the cord has been found in boys and even in infants The onset is sudden with exquisite pain in the testis followed by localised swelling There is often drawing up of the organ, probably due to reflex contraction of the cremaster muscle Then follow nausea, vomiting, chills, fever, and not infrequently pain in the lower abdomen originating in the spermatic cord The temperature in uncomplicated cases is rarely above 100° F, but in some cases may reach 104° With the onset of gangrene the pain diminishes or may disappear entirely In cases in which gangrene does not develop the early tenderness gradually subsides, but for weeks the testicle remains slightly sensitive to deep pressure When the affected testis is in the inguinal canal local and general symptoms are exaggerated and there is often a localised peritonitis The correct diagnosis is rarely made before operation, and depends chiefly on the acuteness of the onset and on the severity of the symptoms, which tend to diminish with the progress of the disease Gangrene or atrophy follow in 86 per cent of cases not relieved immediately Operation before gangrene has occurred has often saved the testis, but it has afterwards atrophied Torsion may be prevented by suturing the undescended testis before puberty to the bottom of the scrotum Treatment consists in immediate operation to deliver and unwind the testicle If the testis and epididymis are viable the cord should be untwisted, the tunica vaginalis inverted, and the organ sutured to the bottom of the scrotum, as was done successfully by Dr Campbell in three cases If the testicle is not viable, orchidectomy should be performed.

THE DUAL NATURE OF VITAMIN B

OBSERVATIONS on the physiological rôle of vitamin B (the anti-beri-beri vitamin) have been conflicting, but J C Drummond and his co-workers at University College are clearing the ground Many of their experiments contradict those of earlier workers For instance, E Abderhalden's claim, that there is a great reduction of oxidative activity in the tissues of animals suffering from beri-beri, could not be confirmed, nor could R A Dutcher's observation that the administration of thyroid extract confers benefit on animals suffering from beri-beri The extreme anorexia for the deficient diet may perhaps be regarded as one of the most important consequences of deprivation of vitamin B Many of the observed symptoms, including lessened metabolism and lowered body temperature, are symptoms of inanition; and when other of the experimental results are interpreted in the light of the great fall in body-weight, which always occurs, many of them lose their significance G A Hartwell discovered[1] a quantitative relation between the amount of protein and the amount of vitamin B which favour normal nutrition The workers at University College have confirmed this, they find that when the amount of protein in the diet is as high as 70 per cent, yeast extract to the amount of 16 per cent is required to obtain normal growth, whereas if the protein is only about 20 per cent of the diet, 4 per cent of yeast extract will suffice C Funk and some of the earlier workers held that there was a quantitative connexion between the amount of vitamin B in the diet and the amount of carbohydrate which could be tolerated, but it now seems that the connexion is with the protein rather than with the carbohydrate of the diet Vitamins continue to multiply and evidence has been obtained that vitamin B, as found in yeast extract, is dual in nature, one part being stable and the other unstable to heat in the presence of alkali, it is the stable fraction which negatives the detrimental effect of excess protein M H Roscoe working at the Lister Institute found[2] that young rats, fed on a diet deficient in vitamin B, collapsed with neuritic symptoms about the twenty-fourth day, the collapse could be cured with alcoholic extract of yeast If the rats continued on the same diet, together with the addition of the alcoholic extract, a fresh and very severe syndrome of "pellagrous" symptoms made its appearance These symptoms, which consisted of loss of hair and œdema, yielded to the administration of yeast autoclaved at 120° C for five hours, which had no effect at all upon the neuritic symptoms The pellagrous symptoms in rats were first described[3] by J Goldberger, who also made the observation that human pellagra is cured by administration of autoclaved yeast It has remained, however, for Roscoe to place the duality of vitamin B beyond doubt

POST-GRADUATE INSTRUCTION AN INNOVATION.

PRACTITIONERS seeking post-graduate instruction fall into several categories of which the two chief consist of senior practitioners seeking to brush up the knowledge acquired as students, and junior men who are endeavouring to secure the highest medical qualifications The rapidly increasing numbers of candidates for the Membership of the Royal College of Physicians of London proves there are many of the second category We are interested to learn that in an endeavour to help such candidates the staff of the Middlesex Hospital has just completed a very successful course, specially designed to provide facilities in advanced clinical medicine Every member of the medical side of the staff took part in the course, which included demonstrations and instruction in dermatology, neurology, public health, medical anatomy and pathology, as well as ordinary clinical medicine Candidates were kept fully occupied from 10 A M until 4 P M daily during four weeks, the main work consisting in examining cases in the mornings and undergoing viva voce examination on them in the afternoons Lectures did not exceed four per week, but the clinical material in the wards was supplemented by the demonstration of many cases selected from out-patients We understand that the course proved so attractive that many candidates had to be refused, even so the numbers were such that it may be necessary to limit them more strictly in the future Different hospitals have their own ways of providing such courses in advanced medicine and it is certainly desirable that they should be readily available The success and popularity of the Middlesex course is good evidence of the constant improvement in medical teaching and of the desire for progress amongst the profession at large

MACULAR COLOBOMA

THE ophthalmoscopic appearance generally known as macular coloboma is the subject of an interesting paper by Miss Ada C Mann in the *British Journal of Ophthalmology* for March According to her the title is a misnomer and she adduces arguments to prove that the defect is not a developmental one at all The alternative view is that the appearance is the result of pathological changes similar to those that are seen following localised choroiditis in adult life The theory that coloboma maculæ may be due to a hæmorrhage at birth cannot be altogether excluded, and in this connexion observations on cases which are definitely known to have shown intra-ocular hæmorrhage at birth are much to be desired The theory that is most favoured by Miss Mann is that macular coloboma is a late result of intra-uterine choroiditis from an infective focus derived from the placental circulation some time between the third month of fœtal life and birth She distinguishes between three types The least rare form of the defect is the pigmented type in which there is heaping up of pigment, destruction of the chorio-capillaries but retention of normal retinal vessels which may course over the patch This type points to a comparatively mild attack of choroiditis or one occurring in the later months of fœtal life. The second and rarer type is non-pigmented, in which all choroidal and retinal structures have been completely destroyed and replaced by scar tissue with generally some ectasia of the sclera. This may be due to a choroidal infection in the earlier months of fœtal life when the tissues are less formed and less resistant to attack. A third type is still rarer in which the macular coloboma is associated with abnormality of blood-vessels. A case has been recorded in which a persistent hyaloid vessel emerged from a macular coloboma. Miss Mann points out that by no possibility could a hyaloid artery enter the eyeball at the macula instead of at the disc, and her ingenious explanation is that at a very early period of fœtal life—before the end of the third month—an inflammatory process beginning in the macular region caused an adhesion of an adjacent branch of the hyaloid artery and that a perforation of the optic cup at the weak spot allowed a ciliary vessel to communicate with this so that it retained its patency long after all other remains of fœtal structures had disappeared. Such studies as these have a practical importance, for if *it can be shown that* certain congenital conditions are infective in origin and not developmental, we are at once able to exclude any relation to an innate hereditary defect in these particular cases.

VACCINES AND THE COMMON COLD.

IN the current number of the *Journal of Hygiene* (vol. xxvi., No. 1) is a paper by Fergus R. Ferguson, A. F. C. Davey, and W. W. C. Topley, describing an attempt to discover whether there is any value in prophylactic inoculation against the common cold. Their results were significant. A population consisting of students of the university and members of the departmental staffs was inoculated during October and November, and the subsequent incidence and severity of colds amongst them was recorded for the period ending on the last day of the following May. The mixed vaccine employed was of a type which has been widely used in this country and contained eight different organisms or groups of organisms; three immunising doses were given at weekly intervals. The experiment was as adequately controlled as it possibly could be, as might be expected in work emanating from the Department of Bacteriology and Preventive Medicine of Manchester University. The population examined numbered 286, of which 138 were immunised and 148 served as controls. Every precaution was taken to ensure that this division was a fair one. For example, a certain number of the population desired to be immunised, whilst others wanted to serve as controls, and it was necessary to guard against the inoculated population containing an undue proportion of individuals who would be influenced in favour of the treatment because they suffered from colds. The relevant facts concerning the fate of the inoculated and the uninoculated are briefly as follows: 138 inoculated persons at risk suffered from 203 colds, giving a mean number of colds per person of 1·47; 148 uninoculated persons suffered from 168 colds, or 1·14 per person. As regards the severity of the infections, the mean duration of the colds in days was 13·0 among the inoculated and 10·7 among the uninoculated, and the percentage of colds associated with fever was 25·1 among the inoculated as compared with 19·0 among the controls. The only possible conclusion is that prophylactic vaccination with the stock vaccine used is valueless, but the investigators are doubtful whether the evidence justifies the conclusion that the inoculations actually did harm. These results are in general agreement with those obtained in two experiments carried out in America in 1921, and constitute a body of evidence which it is difficult to ignore. Influenced by the results of antityphoid inoculations even those who can see little reason to look for good results from therapeutic inoculations have been prepared to accept the value of prophylactic vaccination against colds as well as against many other diseases. But the evidence in their favour has largely been based on uninstructed lay opinion, and Prof. Topley and his colleagues point out that the reports of individual patients are worthless as evidence of efficient prophylaxis; they find themselves in agreement with E. O. Jordan and W. B. Sharp,[1] who investigated the same problem and remarked that "'Satisfied patient' conclusions differ widely from those of controlled statistics." Although the difficulties of adequately controlling methods of treatment in the severer diseases are obvious, the minor maladies are susceptible to a more rigid investigation, and it is to be hoped this type of experiment will be extended. Dr. A. I. Simey suggested not long ago[2] a combined test-effort on the part of medical officers of public schools.

DEATHS FROM DISEASE IN THE CROWN COLONIES.

IN reply last week to a question addressed to him in the House of Commons, the Colonial Secretary supplied a statistical table, singularly complete, setting out the number of deaths attributed to certain specified diseases which occurred in Crown Colonies during the years 1923–25. From this table it is clear that blackwater fever still remains a most potent form of death in the Central African Colonies, especially amongst the European population, and the largest number in a single year (23 in 1925) are recorded from the Uganda Protectorate, while Tanganyika Territory holds the second place in the East, and on the West Coast Nigeria heads the list with a total number of 31 deaths in three years. This most dreaded of tropical fevers hardly features as a cause of death in the other protectorates (of which 39 are cited), save in the case of Malaya, Palestine, and British Guiana. Yellow fever accounted for 19 deaths on the Gold Coast during the period under review, and for 15 in Nigeria. Fortunately it is unknown elsewhere, save in British Honduras where it accounted for one fatality in 1924. Small-pox is recorded as the cause of death in 66 cases in Kenya in 1925, and or numerous others both in East and West Africa, though the returns are obviously far from complete; but no variola fatalities are recorded from the Unfederated Malay States, from British Guiana, or from the West Indies. Epidemic encephalitis has been noted in Kenya (two in 1924), Malta (20 deaths), and the Straits Settlements (2). Epidemic cerebro-spinal fever is the most deadly and widespread according to these returns; thus fatal cases are recorded in all the 39 protectorates and colonies on the list. On the Gold Coast 408 fatalities are recorded, from Uganda 367, from Ceylon 312. Though less prevalent than in West Africa, it is a potent cause of death in the West Indies. It is instructive to note that fatal cases of anterior poliomyelitis are recorded sparingly from Central Africa, the Malay States and Fiji, though the aggregate number from this cause is small (a total of 45 in three years). These are some of the deductions which may be made from figures which must have taken much time and trouble to collect and compile. Those who wish to follow the trend of fatal disease in some of the most important parts of the British Commonwealth should turn to the figures as given in Hansard of April 6th.

MISUNDERSTANDING OF PANEL PRESCRIBING

THE regulation and supervision of prescribing in insurance practice appear still to be misunderstood in some areas. A correspondent who is given prominent place in a responsible Edinburgh journal makes the absurd statement that the total cost of the drugs which a panel doctor may give his patient in a full year must not exceed the sum of 1s. 10d. per person on his list. And he adds, by way of illustration, that 12 doctors were called upon to pay sums varying from £5 to £50 for giving their patients medicines of a total value of more than 1s 10*d* per person on their lists The fact is that excessive prescribing is difficult to define and is only regarded as proven after very careful investigation and review by the panel committee of the area in which the doctor practises In the first instance the figures of the practice under examination are compared with those of the insurance area A striking divergence from the average leads to a minute examination of the prescriptions issued by the practitioner The explanations given by the practitioner of any peculiar or unusual prescriptions are carefully noted and considered by his professional colleagues who know the circumstances of the practice and are in the best position to judge whether the prescriptions are justifiable It is only when the prescriptions given are found to be unnecessarily elaborate or the drugs chosen to be exceptionally expensive or ordered in wasteful quantities that a charge of excessive prescribing can be substantiated The Insurance Acts require that each patient shall receive "proper and sufficient medicine for the adequate treatment" of his illness The practitioner is primarily the judge of what is proper and sufficient, but if the drugs used are unusual in quantity or of exceptionally high cost then the practitioner may be called on by his colleagues to justify the employment of that particular form of treatment, for in the use of public money he must exercise economy, and in the administration of a public fund partly derived from a Treasury grant the authorities have set up machinery for seeing that the money is rightly expended But no hard-and-fast rules have been made and no datum line has been fixed The factors vary with the conditions of each practice and the practitioner is given every opportunity of setting out all the circumstances which in his opinion increase the amount of his drug bill After the panel committee has had the practitioner before them their report is considered by the insurance committee whose function is mainly to see that the standard of treatment of the insured person is not being lowered to the detriment of the service It should hardly be necessary to point out the existence of machinery which safeguards both the patient and the prescriber

[1] Jour. Inf. Dis., xxviii., 357.

[2] THE LANCET, 1925, ii., 1053.

THE Irish newspapers state that the Government of the Free State is in a position to introduce legislation within the next few weeks to settle the question of medical registration within its boundaries It is believed that the scheme to be introduced will be purely domestic, and will be in addition to, and not in substitution for, the present arrangements for registration by the General Council of Medical Education and Registration If the published forecasts are true, a Register will be established in the Free State, under the control of a Council, and any Irish citizen proposing to practise in the Free State will be required to enter his name on this Register On the other hand, it is suggested that persons other than Irish citizens who desire to practise in the Free State will be at liberty to do so, provided their names are on either the Irish Register or the General Register The existing right of entry to the General Register of persons educated and qualified in Ireland will not be interfered with If the proposed changes do not touch on the position and powers of the present General Council, legislation at Westminster will not be required

---

IN connexion with the annual meeting of the French Congress of Neurology and Psychiatry, the Medico-Psychological Society of France has decided to celebrate at Paris, on May 30th and 31st, the centenary of the death of Pinel and of the birth of Vulpian The French Ambassador has asked His Majesty's Government to inform British learned societies of this fact and to convey to them the invitation of the Medico-Psychological Society to be represented at this double centenary Universities, faculties, and societies are asked to furnish the French Ambassador, as soon as may be convenient, with the names of any official representatives whom they may wish to send.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXIX

FRACTURES OF THE CLAVICLE

FRACTURE of the clavicle is a very common injury both in children and in adults Treatment should be directed to the rapid restoration of the function of the shoulder-joint, the actual position of the bones or the deformity being a secondary consideration It may be that sometimes the prevention of deformity is considered to be of paramount importance, but these cases, usually young women, are exceptional and require special treatment

Bad results after fractures of the clavicle are nearly always the consequence of elaborate methods of immobilisation intended to "set the fracture" correctly, which tie the arm to the side for a long period and so produce stiffness of the shoulder A consideration of two types of case will serve to prove the contention that preservation of the function of the shoulder-joint is much more important than elaborate fixation of the fragments In the first place, patients from whom, for some reason or other, the clavicle has been altogether removed, whether for new growth or osteomyelitis, show excellent and unimpaired function of the arm and shoulder, in the second place, the victim who survives an accident so serious that because of other injuries the broken clavicle has had no treatment but a simple sling will have a perfectly strong arm, though the collar bone may have united with some degree of angulation and with much excess of callus

Fractures without Displacement

In all those cases, therefore, in which fracture of the clavicle is unaccompanied by displacement no immobilisation is required This applies both to greenstick fractures in children and to fractures of the outer end of the clavicle in the neighbourhood of the coraco-clavicular ligaments in adults The arm should be supported in a sling which should take a good hold of the elbow and support the weight of the limb Every day light massage should be applied to the neck, shoulder muscles, and arm, and the limb should be lifted up to a position of full abduction and supported in this position during most of the massage treatment In three weeks to a month firm union and good function should be secured.

Fractures with Moderate Displacement.

The main problem of treatment concerns cases of fracture of the middle of the clavicle with marked displacement of the bony fragments The sternal end of the bone is drawn upwards by the sterno-mastoid muscle, whilst the acromial end is displaced downwards by the weight of the arm and inwards by the pectoralis major It is not easy to influence the position of the sternal fragment, and treatment must therefore be directed to bringing the distal or outer fragment into as good alignment as possible with the inner end of the bone Two adjustments are necessary—viz, the lifting of the shoulder which takes the outer end of the clavicle with it, and the pulling of the shoulder backwards, so as to exert traction on the clavicle and reduce the inward displacement of its outer end. Both these adjustments are usually quite easy, even without the use of an anæsthetic, although the latter may be necessary in the case of a nervous, frightened patient It is, however, more difficult to maintain this reduction than to effect it in the first place The time-honoured methods which have found so conspicuous a place in text-books consist in fixing the arm to the chest by means of bandages or adhesive strapping But these methods are quite contrary to the principle of conservation of the shoulder-joint function, which, as explained above, should be the main object aimed at Particularly is this true of Sayre's method in which after shaving the chest the arm and chest are enveloped in adhesive plaster and so left for several weeks

The most important act in adjustment of the fracture is the backward pull of the shoulder The surgeon should stand behind the patient and pull both shoulders back, keeping the body in position, if necessary by means of his knee placed between the shoulder-blades Whilst the shoulders are strongly held back, they are fixed in this position by a figure-of-eight bandage which goes over each shoulder and under each axilla, crossing over the middle of the back Or, instead of the simple bandage, a straight splint may be applied across the back of the shoulders which are then tied back to it It is a matter of opinion whether the simple bandage or the splint is the more efficient method and a few further words may be said about each The figure-of-eight bandage ought to be put on over a vest, which will prevent the skin from becoming rubbed or sore The bandage itself should be of stout material—e g , calico—so that it will not stretch, and if in an out-patient there is any doubt as to its being tampered with, it is wise to use a wet starched bandage (made from crinoline muslin) The splint is perhaps neater and lighter than the bandage if it is made of a piece of three-ply wood, but it is apt to get out of position if the patient is at all round-shouldered, when the splint rides upwards This should be prevented by the use of adhesive strapping which fixes the splint to the body below.

After the backward adjustment of the shoulder has been made and fixed, the arm as a whole is raised and so supported by a firm sling, which runs under the elbow and over the opposite side of the neck It is better to have this made of a band of calico or other firm material 6 inches wide than to trust to the ordinary triangular sling The band sling should be securely adjusted at the elbow (making a slit or pocket in the sling for the bony joint) and both elbow and the neck should be protected by soft felt or wool from undue pressure

After-treatment —After the fracture has been adjusted and fixed an X ray should be taken to determine the relative position of the fragments, which may if necessary, be modified when the bandages are readjusted But it is quite unnecessary to secure perfect anatomical restitution and a certain amount of overlapping or of angulation can be ignored without fear of a bad result The third day after the accident, and on every following day, the arm is released from its sling and some massage and movements administered The method and degree of this after-treatment are very important and should only be undertaken by a responsible person accustomed to work with the surgeon Careless manipulation quite defeats the object of the treatment and if a trustworthy masseuse is not available it is much better to leave the arm untouched for a week or for the surgeon himself to undertake the dressing For the first week or ten days (we are still considering a case where there was marked displacement) the daily after-treatment should be carried out with the patient in a recumbent position on a hard couch with the affected shoulder over the edge In this way the tendency for the shoulder to drop down or to be pulled forwards will be prevented The figure-of-eight bandage or the back splint need not be disturbed The sling is removed from the elbow, massage is given to the muscles of the neck and arm, and the shoulder is gently moved to a moderate degree of abduction This abduction movement need only be done once in each treatment After about ten days or a fortnight the bandage and splint may be removed from the back of the shoulders and the treatment carried out with the patient sitting up

Fractures with Considerable Displacement

If the displacement of the fracture should be considerable, taking an upward and forward angulation, and if this occurs in a leisured person it may be wise to begin the treatment by a week or two in bed The mattress should be firm and hard, the patient should lie at the side of the bed with the shoulder and arm over the edge supported on a stool which is on a level lower than that of the bed In this way the weight of the arm makes the shoulder fall outwards and backwards, and as the muscle spasm subsides the bone comes to lie in a good line

Complications

There is probably no long bone in the body the fractures of which are so seldom accompanied by serious complications, or which so seldom require operative treatment Text-books all mention an alarming list of possible special complications of fracture of the clavicle, these being injuries to the brachial plexus, the subclavian vessels, and the pleura or lung It is true that such injuries may be associated with a break of the collar bone when a severe direct blow has been received on the shoulder or over the root of the neck We became familiar with these complex injuries during the war But in any such composite injury, the fracture of the clavicle is only a minor incident and its treatment should be relegated to a secondary place The idea that splinters of the broken bone may be driven into the vessels, nerves, or pleura is probably far fetched if not entirely imaginary, whilst the idea that excess of callus may cause injurious pressure on these structures is still less supported by fact

Non-union of a fracture of the clavicle is exceedingly rare, so much so that its possibility may be ignored For these various reasons open operative treatment of the fractured clavicle is practically never required unless an exposure is demanded for some other reason, and then the broken bone may be fixed by some form of internal fixation, the use of kangaroo suture after drilling being generally the best

SCIATICA.

BY JOHN H ANDERSON C M G, C B E,
M D MELB,
PHYSICIAN, RUTHIN CASTLE (DUFF HOUSE)

THE term sciatica is generally used to describe pain referred to the roots, trunk, or branches of the sciatic nerve Sciatic pain may arise from many causes, and the first step in treatment should be an attempt to make as accurate a diagnosis as possible regarding the nature of the cause and its position It is only when this has been done that the practitioner can embark on a line of treatment which he can follow with peace in his own mind and with real benefit to his patient

The sciatic nerve springs from the fourth and fifth lumbar and the first and second sacral spinal nerves, and is widely distributed over the lower limb, both to muscles and skin

Ætiology

Pain in its area of distribution may be caused by —

A.—Causes within the nerve sheath

1 Localisation of a polyneuritis

(*a*) Diabetes (degeneration in nerve filament)

(*b*) Alcoholic or arsenical poisoning (parenchymatous degeneration of small terminal branches)

(*c*) Lead poisoning (degeneration of motor neurons)

(*d*) Syphilis, especially in tabes dorsalis (degeneration the afferent neurons in the posterior spinal roots)

(*e*) Gout

(*f*) Diphtheria (acute degenerative changes in cord)

(*g*) Anæmia

(*h*) As a sequel to herpes zoster involving the sciatic nerve (spinal ganglia affected)

2 New growth involving nerve sheath. syphilitic, tuberculous malignant &c

3 Neurofibrositis (Syn interstitial neuritis or perineuritis of the sciatic nerve, sciatic neuritis, idiopathic or essential sciatica)

B —Causes outside the nerve sheath

1 Pressure

(*a*) Direct pressure, sitting on hard seat, unconscious patient "lying on nerve"

(*b*) Fœtal head during, *or forceps* at termination of, pregnancy

(*c*) Tumours of pelvic girdle or tumours arising in pelvis Includes malignant, syphilitic, or tuberculous disease of lower part of spine or sacrum, carcinoma of rectum ovary, uterus, ovarian cyst, fibromyomata of, or retroverted uterus, tumour or meningitis of lower part of spine or cauda equina, pelvic gummata, psoas abscess, callus after fracture

(*d*) Constipation

(*e*) From static abnormalities, producing an effect through muscular contractions, as in flat-foot and perhaps spondylitis deformans

2 Referred pain

(*a*) Hip joint or sacro-iliac disease, septic, tuberculous, or rheumatic This may also act by direct spread to nerve sheath

(*b*) Knee-joint disease

(*c*) Local irritation at any point of distribution of the nerve

The above furnishes a working classification, but the mode of action of a specific cause may, of course, vary from time to time Thus in spondylitis *deformans* it is doubtful whether the cause of pain in the sciatic nerve is a neurofibrositis, due to the toxin or infection which produces the spondylitis deformans or to irritation of nerve roots, or a pressure effect following a viscero-motor reflex on the part of the adjacent muscles

Differential Diagnosis

The differential diagnosis is often very difficult, but the following points may be noted In diabetes the urine and the blood-sugar should be examined, alcoholic and arsenical poisoning, the history, lead poisoning the gums, and blood for a punctate basophilia, diphtheria the history and cultural examination of nose and pharynx, anæmia, the blood, gout, history. and examination of joints blood uric acid, herpes history and signs of recent scarring, in pelvic tumours as a rule pain is bilateral, less severe, and not limited to distribution of sciatic nerve, tenderness absent after pressure on or stretching nerve, loss of function is early patches of anæsthesia or paresis correspond to root rather than to nerve distribution may be primary elsewhere particularly breast or testicle, rectal and vaginal examination necessary, tumours of cauda equina often show disturbance of rectal or vesical sphincters; in psoas abscess there is inability to extend leg backwards without pain, X ray examination (with stereoscopic and lateral views) is necessary to exclude bony or articular disease of lower part of spine and pelvis, syphilis is shown by history and blood Wassermann reaction in osteo-arthritis of hip-joint X ray is useful and the patient is unable to bear backward pressure on the knee when it is flexed and outwardly rotated so that the foot of the affected side rests on the knee of the sound side These are some of the points to be considered in separating a neurofibrositis of the sciatic nerve from conditions which may simulate it

J P Martin (in THE LANCET of May 22nd, 1926 p 991) puts the position shortly as follows —

> "Most diagnostic errors will be avoided if it is remembered that (1) in sciatica the inflamed nerve is always tender, (2) since the sciatic nerve sends no branches to the front of the thigh any condition in which the pain extends to the front of the thigh or groin is not sciatica alone, (3) sciatica causes no muscular paralysis and no gross sensory loss, (4) it may abolish the ankle-jerk but never the knee-jerk"

Sciatic Neuritis

True sciatic neuritis or neurofibrositis is characterised by changes in the connective tissue which surrounds and binds together the nerve-fibres into nerve trunks The parts affected become swollen and pink, the sheath is distended, and when the inflammatory process subsides there is cicatrisation which frequently causes permanent shortening of the nerve trunk

The pathological condition explains why the pain is generally unilateral, more or less constant, worse on movement coughing or stretching the nerve, and not completely removed by absolute rest, as is the case in lumbago In addition, tenderness is present on pressure over the nerve Treatment should be directed to removal of the cause, when it can be found, as well as to palliative treatment during an attack.

The common causes of sciatic neuritis may be set out in the following groups —

1 Toxic or infective

(*a*) The toxins of acute infections as influenza, malaria, &c

(*b*) From foci of infection elsewhere in body Any chronic infection may act as a primary, but the most usual sites are head sinuses, teeth, tonsils, gall-bladder, kidney, urinary bladder, and, lastly, the alimentary tract as in appendicitis, colitis, diverticulosis, or chronic constipation

2 Exposure to colds and chills, the so-called "rheumatic group"

3 A group associated with spinal disease, particularly spinal arthritis and sacralisation (bony union between the transverse process of the fifth lumbar vertebra and the sacrum)

4 Infection following direct injury as in stabs or gunshot wounds

Continental writers place great stress on the association of spinal arthritis and sciatic neuritis Putti lays down that essential sciatica is synonymous with spinal arthritis Such arthritis is regarded as being generally secondary to congenital abnormalities in the articular facets of the lower lumbar vertebræ Sicard holds that the funicular parts of the fourth and fifth lumbar spinal nerves are involved as they pass through the intervertebral foramina in close relation to the vertebral bony articulations Disease in these articulations may cause pain in the adjacent nerves either by pressure or by direct spread, and can only be detected by stereoscopic and lateral X ray examination

It will be seen, then, that the preliminary treatment of "a case of sciatica" may, in addition to a careful history and clinical examination, demand a great deal in the way of special investigation, including X ray examination of head, teeth, gall-bladder (cholecystography), alimentary canal by opaque meal and enema and of pelvis and spine; an examination of the blood including a Wassermann reaction cultural examination of urine and fæces and investigation of any system or organ to which attention may be directed by the history or physical examination

Treatment of an Attack

General management—The patient should remain in bed, in a warm, well-ventilated room, with the affected limb covered by a special bed sock, and, if necessary, the hip enclosed in a light cotton-wool or thermogene dressing While a soft bed is generally preferred it should not sag so as to cause lateral flexion of the lower spine Splinting is theoretically right but, as a rule, wrong practically, though the leg may be held in place by sandbags or by a pillow between the knees The diet should be light and nourishing, containing plenty of fruit and vegetables if constipation is suspected Alcohol is not advised

Local treatment (*a*) *Anodyne*—Heat is always grateful either as a poultice, hot bricks or sandbags, radiant heat, antiphlogistine, hot-air baths, or the humble hot-water bottle If special appliances are used, a treatment towards bedtime will often help to promote sleep The application of belladonna, mesotan, or analgesic balm along the course of the nerve is sometimes soothing Where other measures fail dry cupping may give relief

(*b*) *Counter-irritant*—Blisters, painting with iodine, or a stimulating liniment have their advocates, but should be used with great care lest a local skin condition be produced, and the last state be worse than the first

(*c*) *Massage*—In the early stages the only massage tolerated is of a light superficial nature, and is most soothing when combined with a radiant heat bath Later on, deep massage may serve to break up nodules and loosen adhesions, but must always stop short of causing subsequent pain

Electrical and injection treatments—These have been fully dealt with by Dr J P Martin in THE LANCET (*vide supra*) This excellent article gives full details, and the present writer can only suggest that in some cases ionisation does seem of value, when other means fail, and that diathermy across the pelvis will occasionally bring relief

Medicinal—Certain drugs are thought to influence the duration of the attack, and among these the iodides hold pride of place A convenient form is Lugol's solution, starting with a drop in a table spoonful of water, three times a day, increasing three drops a day, till 30 drops are taken daily and then reducing at the same rate An alternative is to give ten drops of the tincture of iodine in milk night and morning gradually increasing the dose up to 25 drops and then decreasing In late stages of the attack the combination of guaiacum and sulphur is useful, either as confectio guaiaci co (the well known "Chelsea pensioner") or as tabloid guaiaci et sulphuris (B W and Co) A combination the writer has found useful is pot iod, gr v, sod salicyl, gr x, tr nuc vom, ♏ v, aq chlorof ad ʒss

To relieve pain aspirin, pyramidon, codein, heroin, and morphia are all employed according to the severity of the pain A useful prescription is pulv empirin, gr viii, phenacetin, gr v, sp chlorof, ♏ iii, syr zingib ♏ xv, mucil q s, aq ad ʒss, or as a capsule containing caffein 2 gr, aspirin, pyramidon, and phenacetin 1 gr of each

To aid sleep one may use barbitone, adalin, medinal, allonal, &c The pain is generally worse at night and the time of its incidence will control to a certain extent, the choice of hypnotic A good plan is to give the analgesic half an hour before the hypnotic and if the pain comes early in the night use bromural medinal, or adalin, which act quickly Trional is slowly absorbed, and is most useful when the pain is worst in the early hours of the morning

Surgical—Acupuncture of the nerve sheath is said to be of use during an attack to disperse the exudate, but I have no personal experience of its use When the chronic stage is reached open operation may be necessary to free the adhesions left as a result of the inflammatory process The best results are obtained in those cases where pain is not complained of while the patient is at rest, but is acute on movement, or on placing the limb in certain positions If the adhesions are slight, simple stretching of the nerve may be sufficient

Radiation—Exposure to X rays or ultra violet rays have proved of use in some cases.

Special treatment—This is directed to the removal of any cause, and the time of its application will depend on the nature of the trouble and the state of the patient As a general rule, the sooner any focus is dealt with the better If spinal arthritis is present splinting of the lower spine and pelvis is advocated about the third day A plaster jacket is used for the first two to three months and later a celluloid or similar corset In some of these cases laminectomy to enlarge the intervertebral foramina has been successful

GENERAL MEDICAL COUNCIL.

EXECUTIVE COMMITTEE

AT a recent meeting of the Executive Committee official notification was received of the reappointment of the following members of the Council Dr John Yule Mackay (as representative of the University of St Andrews for five years from Jan 7th, 1927), Sir Arthur Chance, F R C S I (as representative of the Royal College of Surgeons in Ireland for one year from Jan 31st, 1927), and Mr Herbert Lightfoot Eason, M S (as representative of the University of London for one year from Feb 24th, 1927)

Restorations to the Register under Section 14

The following names, erased owing to failure to reply to the Registrar's inquiry, were restored to the Medical Register —

Theodore Bloomenthal, Frank G Cory, Jesudason S David, Alfred L V Davin, G M Earle, G W B Featherstone, Thomas W George, M Grundy, H Hardwick Smith, E B Jones, B W R Divarka Kamalakar, Clayton A Lane, E E McCulloch, Lancelot G McCune, M McGann, James J McKee, Herbert W G McLeod, R M McQueen Ernest Martyn, Wm Miller, Lionel C F Murphy, Albert O Nixon, John Spencer-Daniel, William H Stott, M E Thomson, and J F W Waters

Instruction in Midwifery at Calcutta.

It will be remembered that in 1924 the University of Calcutta failed to satisfy the Council as to the adequacy of instruction given in its two medical colleges, and that in consequence recognition of the medical degrees of Calcutta University ceased on Nov 30th of that year A letter from the Vice Chancellor of the University, dated Jan 27th, 1927, now reported that the University had adopted all the suggestions for the improvement in instruction and standard of examination made by the Council in 1924 that these had been embodied in the Regulations, and would come into operation from 1927 onwards The Council minuted its pleasure at the receipt of this information and deferred further consideration until May, when Sir Norman Walker and Colonel Needham would be able to report personally

Practice in Mauritius

A communication was received from the Colonial Office transmitting a proposed Bill to regulate the practice of medicine and surgery in Mauritius This Bill makes it unlawful for other than duly registered medical practitioners to practise medicine, surgery, or any branch thereof in the Colony, it provides for the registration of any person who holds a diploma entitling to registration in the United Kingdom, or a diploma of Doctor in Medicine of the Faculties of Paris, Montpellier, Bordeaux, Lyons, and Lille, provides for the erasure of a person convicted of an offence which, if committed in the Colony, would be a felony or misdemeanour, or guilty of infamous or disgraceful conduct in a professional respect, permits qualified midwives, dentists, or veterinary surgeons to exercise their respective professions The Executive Committee expressed gratification that Mauritius is taking steps to prevent the practice of medicine by unqualified persons, and informed the Colonial Office (in response to an inquiry) that the L M S diplomas of the State Medical Colleges in India are not recognised as entitling their holders to registration in this country

Reciprocity with North-West Territories, Canada

A communication was read from the Director of the Department of the Interior, Ottawa, transmitting the Medical Profession Ordinance, 1898 together with two Amending Ordinances of 1903 Section 29 of the Ordinance provides for the registration of persons holding diplomas obtained in Great Britain, subject to passing an examination In 1919 the Council extended reciprocity to members of the C P & S of the N W T, and the C P & S of Saskatchewan undertook to issue duplicate certificates of registration to such members as obtained the licence of the N W T after examination Now that reciprocity with Saskatchewan has been rescinded, this arrangement is deemed to have ceased

Professional Practice in the Sudan

A communication was read from the Director of the Sudan Medical Service transmitting the Public Health Ordinance 1924 This Ordinance provides that no person shall exercise the profession or calling of physician, surgeon, dentist pharmacist druggist, or veterinary surgeon except by virtue of a licence granted by the Director of the Medical Department on the recommendation of the Central Sanitary Board in the case of a physician surgeon, dentist, pharmacist, or druggist and by the Director of the Veterinary Department on the like recommendation in the case of a veterinary surgeon Exception is made for any qualified professional man employed by the Government or in the British or Egyptian Army Any person contravening is liable to a fine not exceeding £E 50 or to imprisonment for a period not exceeding six months Section 73 provides a fine not exceeding £E 10, or imprisonment not exceeding three months for any person other than a physician or surgeon licensed under the Ordinance who prescribes, treats or professes to cure venereal disease, or advertises for sale any remedy which is represented as a cure for such disease

Dangerous Drugs Regulations

A communication from the Home Office was read stating that the Under Secretary of State had appointed Sir Humphry Rolleston to be Chairman of the Medical Tribunal for England and Dr A W Mackintosh to be a member of the Tribunal for Scotland, with Dr Wardrop Griffith and Dr Wild substitutes for England, and Dr Adams substitute for Scotland Sir Robert Philip had been appointed Chairman of the Tribunal for Scotland, and Mr E W. Hansell, M A and Mr John Cowan K C, had been appointed Legal Assessor to the English and to the Scottish Tribunal respectively

British Institute of Radiology

The Committee approved of No 12 of the Articles of Association submitted for comment by the Board of Trade, to the effect that no member or associate of the Institute who is not a registered medical or dental practitioner shall accept patients for medical diagnosis or treatment except under the personal supervision of a registered practitioner The Committee suggested to the Board that Section 3 (c) of the Memorandum of Association, which provides for granting diplomas and certificates of merit and efficiency, should be amended by the addition of the words. "and that the holder of such diploma or certificate is not thereby entitled to undertake the medical diagnosis or treatment of patients except under the personal supervision of a registered practitioner"

Medicines and Drugs.

Sir George Newman, who had undertaken to ascertain what drugs and solutions were referred to in the Rules of the Central Midwives Board (No C 5 *q*) on which instruction was to be given, and whether any directions were given as to what drugs the midwife might or might not use in her practice had forwarded the following resolution adopted by the Central Midwives Board at its meeting on Jan 6th, 1927 :—

> "That a midwife is expected to possess competent knowledge of the drugs and solutions used in obstetrics This instruction is part of her education by the approved teachers The Board has never scheduled drugs which may or may not be used by midwives, having regard to the differences of opinion held by recognised authorities The midwife is obliged by Rule E 19 to 'note in her Register of Cases each occasion on which she is under the necessity of administering or applying in any way any drug other than a simple aperient, the name and dose of the drug and the time and cause of its administration or application,' and is answerable [to the Board] for the improper use of any drug"

The Committee resolved that it is expedient that the rules of the Central Midwives Board should include provisions restricting the drugs and solutions to be used by midwives in their practice, and decided to forward a copy of this resolution to the Ministry of Health and the equivalent authorities in Scotland and Northern Ireland

Amendment of Warning Notice No 7

In view of the provisions of the Midwives and Maternity Homes Act of 1926, the Executive Committee decided to recommend amendment of the Warning Notice relating to Association with Uncertified Persons practising as Midwives, by inserting the italicised words —

> "Whereas it has been made to appear to the Council that certain registered medical practitioners have from time to time by their countenance or assistance or by issuing certificates notifications or other documents of a kindred character knowingly enabled uncertified persons on pretence that such persons were under their direction *and personal supervision* to attend women in childbirth contrary to law and whereas such conduct is in the opinion of the Council discreditable to the profession of medicine, and calculated to defeat the purpose of the Statutes made in the public interest for the protection of mothers and infants, notice is hereby given that any registered practitioner who is proved to have so offended will be liable to have his name erased from the Medical Register"

LEEDS GENERAL INFIRMARY —The annual meeting was held on March 30th The report presented makes clear the urgent need for an increase in the voluntary hospital accommodation in Leeds The infirmary at present provides 531 beds and cots, supplemented by 68 beds and cots at the Robert Arthington and Ida semi-convalescent hospitals These two hospitals are not ordinary convalescent hospitals but really extensions of the infirmary to which patients especially surgical ones who require a continuance of hospital treatment, can be transferred The list of patients waiting for admission to the infirmary is very large, and the increase in the patients in the extern departments, whose numbers are not limited by the number of beds, emphasises the necessity for more accommodation An effort will shortly be made to add two new three storied blocks, each with about 100 beds, within the grounds of the infirmary It is suggested that one at least of these blocks should be allocated to paying patients The dental school and hospital are now in close connexion with the infirmary. When the dental school outgrew the accommodation provided for it at the Leeds public dispensary, the infirmary was able to place at its disposal the large out-patient hall which had been replaced by a new department This hall forms an admirable temporary accommodation Some time ago the building of a properly equipped dental hospital was started by the combined efforts of the infirmary, which has provided the site of the University, which has met some of the cost, and of the Dental Board and the local dental profession

THE LISTER EXHIBITION.

RECEPTION AT THE WELLCOME MUSEUM

ON April 7th some 100 people attended an evening reception at the Wellcome Historical Medical Museum, Wigmore-street, London Addresses on the Lister Centenary were delivered by Sir William Watson Cheyne *and others, and an excellent exhibition of* Lister relics was on view The Austrian Ambassador and the Argentine Minister were amongst the guests, and the medical profession in London was fully represented Amongst the many present who personally knew Lord Lister was Mr Henry Jones, whose age is 87, and who was butler both to Lord Lister and to his father before him over a period of 50 years The guests were received by Sir W Watson Cheyne, supported by Sir StClair Thomson and Prof Archibald Young, and assisted by Dr C M Wenyon, Director in Chief of the Wellcome Bureau of Scientific Research, Dr S H Daukes, Director of the Museum of the Bureau, and Mr L W G Malcolm, Conservator of the Wellcome Historical Medical Museum

In the absence of Mr H S Wellcome, Sir W WATSON CHEYNE presided It was a pity, he said, that when Lister came to London he had not found the appreciative atmosphere of the past few days, in such an atmosphere his work would have gone much further It was, perhaps, surprising that during the centenary celebrations no allusion had been made to Lady Lister, for it was difficult for those closely associated with Lord Lister and his wife to think of one without the other She was his only secretary, and they discussed his views on an almost equal footing For hours, day and night, she would sit *waiting to take down anything that occurred to him* and noting his observations

At the time when Lister began to work, continued Sir W Watson Cheyne, practically no one else was doing anything except a repetition of Pasteur's experiments, and Lister also repeated these experiments He found that insufficient attention was paid to sterilisation of the vessels in which experiments *were performed, and he himself constructed the hot box* for sterilising the flasks, which was superior to any method hitherto in use After demonstrating the results obtained by Lister in his bacteriological experiments, Sir W Watson Cheyne concluded by saying that this official Centenary Exhibition served to emphasise one of the vital purposes of the Wellcome Historical Medical Museum—namely, to demonstrate *and visualise to research workers, students,* and others the achievements and methods of workers in medicine, surgery, and the allied sciences It was remarkable in its interest and in its completeness Mr Wellcome regarded the Museum as in its infancy, and destined it to be an institution of a vigorously progressive nature permanently located in London, for London was the medical centre of the English-speaking world and also the appropriate location of Sir William Osler's projected post-graduate institution and fellowship of medicine

Prof ARCHIBALD YOUNG *described his share in the* centenary as partly due to his occupancy of the Regius Chair of Surgery in the University of Glasgow, which from 1860–1869 was occupied by Lord Lister, and partly to the regrettable absence of Sir Hector Clare Cameron, who felt himself unable to face the journey to London and had asked him to come instead

Beaconsfield had somewhere said, continued Prof Young, that "one of the greatest legacies of any nation is the memory of a great name, and the inheritance of a great example" This was equally true of a seat of learning The University of Glasgow had a long and glorious record, the traditions of well-nigh 100 years clustered around the names of men who had done much to advance its efficiency and repute In the long and distinguished roll, however, no name outshone that of Lister, whose tradition rendered illustrious for all time its Regius Chair of Surgery The story of the birth of the antiseptic system had been often told, and would be told through the ages It was true that others before Lister had had some inklings of the truth Semmelweis, in 1847, had traced puerperal fever to infection, Lemaire, in 1863, in a treatise on carbolic acid, had advocated its use for the destruction of germs in wounds, whilst Bottini, in 1866, had urged *that carbolic acid should* be employed in the treatment of suppuration But *it was none the less true that it was Lister that finally* solved the riddle of wound infection and its prevention, it was Lister who was able to work out fully the whole problem There was no need to tell the story again Was it not told in the best of all ways in this great historical exhibition? Illustration was always worth much more than speech in elucidating a problem or in impressing a truth, and here was a *wealth of illustration Changing the simile, it might* be said that the promoters of this Museum had constructed in miniature a picture of the great life-work of the Master, a picture in which, with judicious selection yet with sufficient generosity of emphasis were portrayed the successive steps by which was built up the mature doctrine of antiseptic surgery it was to-day

Prof Young then went on to speak of the revolution in surgery at Glasgow which Lister's work had brought about The idea that, by improved ventilation and such means, it was possible to banish the dire hospital diseases which were now known to be due to infection by pyogenic germs had not been easily eradicated When Lister left Glasgow for Edinburgh he published a paper dealing with the Effects of the Antiseptic System of *Treatment upon* the Salubrity of a Surgical Hospital,[1] in which he declared that the antiseptic treatment had transformed *the wards under his care in the* Glasgow Royal Infirmary from among the most unhealthy in the country into "*models of healthiness*" Voicing the opinions of the managers of the infirmary, the irate Secretary wrote [2] to point out that the improved healthiness of the wards was to be *ascribed mainly* to "better ventilation, improved dietary, and the excellent nursing to which the Directors have given so much attention of late years"

In the earlier years, after Lister began to promulgate *his new theories in practice,* he had met with apathy and even hostility in Glasgow, as well as in Edinburgh and London, for the promulgator of any new doctrine was generally received coldly—and was liable to be misjudged, maligned, opposed and even at times painfully misrepresented This traditional fate Lister did not escape

But though he might be grieved by the opposition he encountered, he had not been dismayed Always he was his own most severe critic, and a piece of reasoning, if it had passed the bar of his own scrupulous *and searching criticism, was hardly open any longer* to effective attack Moreover, though he encountered in Glasgow, Edinburgh and London the chilling effects of apathy and indifference, yet in the two *former* places at least he was supported with uniform enthusiasm by large classes of students and was served always by loyal dressers and assistants, who, like Sir Hector Cameron, believed in him and in his message with their whole hearts and promoted its *practice to the utmost On appointment to the* Regius Chair of Surgery at Glasgow in 1860 Lister found himself without any direct hospital connexion To secure clinical material for his teaching he had to await a vacancy on the staff, and even then to take his *chance of election in competition with other applicants* At the first attempt he was unsuccessful Then a thing happened which the students of surgery in *Glasgow to-day were glad to recall In Lister's* first session after appointment he lectured to a class of 182 students and at the close of the session the class took the altogether unusual course of presenting him with an address, expressing their appreciation of his teaching and expressing their hope that "for the sake both of the rising profession and of the Institution itself" his application for the next vacancy on the staff of the Royal Infirmary would be successful This address was meant to be a testimonial in support of his application and was signed by 161 members of his class It was preserved amongst the exhibits, and Prof Young had been glad to find among the signatures those of an uncle of his wife, and of an uncle of his own—William Loch Stuart and John Young

[1] THE LANCET, 1870, i 1 et seq

[2] Ibid, 1870, i, 175

Sir **StClair Thomson** remarked that "after these days of praise and adulation, fellows of the baser sort will be thinking that it is time we began to hear of some of Lister's defects" The defects of the great were the consolation of mean men The curious thing was that people did not feel mean in Lister's presence His was an outstanding example of how, by treating all his opponents with courtesy and patience, he appeared to elicit from them, however narrow-minded and bigoted, some of the same patience, toleration and hunger for truth Only by cudgelling his brains was he able to think of Lister's defects, and he could only remember two or three very trivial ones He had no sense of time, he was apt to be late for appointments, and he was still working at and polishing up his address when the carriage was at the door waiting to take him to the lecture hall Another defect was that "he joked with deefeeculty" He was also what would be called in these days of the æsthetes, "very utter and and intense" He had no absorbing hobbies, like golf or bridge, although it was known that he skated, fished, was devoted to walking and excursions, was fond of botany and bird life, and could be as happy as a boy when on a holiday. But at an evening party no fish out of water ever looked more unhappy and miserable He was wise in that with him, "true companionship came from sharing in work" He was exceedingly hospitable without ostentation to all who worked under him, visited his clinic, or shared in any of his labours The happy circumstances that he had had a sufficient fortune had not turned him to idleness, but helped to explain why he was not a success as a consulting physician in London He would decline to name a fee, or else suggest such a modest one that he put the family practitioner in an embarrassing position

Sir StClair Thomson went on to speak of the exhibition It demonstrated that this genius could be methodical, orderly, cautious, and far-sighted even to the verge of pernicketiness All these wonderful souvenirs would be a source of inspiration for future workers in science and surgery The man who looked forward was apt to see only one road to advance The man who also looked backward could see two or more possible avenues for advance The generosity and wide view and the unselfishness of Mr Wellcome had opened up both roads Sir StClair Thomson wished that he were there so that heartfelt thanks might be tendered for his generous hospitality, and so that he might be assured of their deep appreciation of his great work

A vote of thanks to Sir W Watson Cheyne, Sir StClair Thomson, and Prof Young was proposed by Sir **John Samuel**, Honorary Secretary, Glasgow Lister Memorial Committee, who described Lord Lister as a great gentleman and spoke of the consideration with which he had been treated by Lister when he was a young man Glasgow, in spite of the destruction of the Lister ward, was not forgetful of his work

The vote was seconded by Dr **Pasteur Vallery-Radot**, grandson of Louis Pasteur, who spoke of the interpendence of discoveries and discoverers Pasteur could not have done his work but for Jenner, and Lister could not have done his without Pasteur Between these two men there had been great personal affection

A vote of thanks to Mr Wellcome was passed with enthusiasm on the motion of Sir **StClair Thomson**

The company then proceeded to view the Exhibition itself, which contains a section of the original ward of the old Glasgow Royal Infirmary in which Lister carried out his work It has in it the furnishing and equipment used in Lister's time, and presents an epitome of the evolution of antiseptic surgery Very many of the exhibits are the actual materials and appliances with which Lister worked There is a complete collection of the various types of sprays and dressings he devised and also an exhibit of his bacteriological apparatus The insignia of Lord Lister's orders, the freedoms of cities, and the diplomas and other distinctions granted him are also on view as well as a large collection of portraits and letters

THE LISTER CENTENARY

THE TESTIMONY OF WILLIAM WILLIAMS KEEN

The ninetieth birthday of Prof William Williams Keen, of Philadelphia (he was born on Jan 19th, 1837, that is to say, while William IV was still on the throne), was recently celebrated by a service of congratulation conducted under the auspices of the First Baptist Church of Philadelphia, of which congregation the veteran surgeon had been an active member from childhood At the close of the addresses conveying the affection and esteem of the congregation Prof Keen gave a brief and modest outline of his own career tracing with convinced piety the guidance of God in shaping his aims, their successes, and even their failures Of Lister's approaching centenary he said, "In 1876 Lister was President of the Surgical Section of the International Congress of Medicine, held in Philadelphia in connection with the Centennial Exhibition He explained his antiseptic system of surgery so convincingly that I instantly accepted it. I was his first disciple in this city Each succeeding year has only strengthened my conviction of its enormous value to mankind and to animals in every department of medicine Hence, compound fracture of the leg, in competent hands is a 'safe accident' to day Any surgeon who now loses more than 3 or 4 per cent of his cases of ovariotomy must critically examine his methods if he is to maintain his standing among his fellow-surgeons Before Lister's day *Noli me tangere* was writ large on the head, the chest and the abdomen We never dared to invade these cavities in my early surgical days unless accident had already opened them To-day they are the arena of our chief victories Even the brain and the heart, the very citadels of life, surrender at our summons The labors of Lister and his followers have changed the Purgatory of my early surgical days when death peered over the shoulder of the surgeon at every operation and was sure of abundant victims, to the Paradise of to-day, when almost every death following an operation is a 'surprise,' which bids us search for any possible error in our technic"

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

Small-pox in Dundee

The detailed report on the Dundee outbreak of small-pox—up to date there have been some 77 cases[1]—will be an interesting document It will show how puzzling some recent varieties of small-pox can be, but it will also show how an outbreak can be controlled when it is properly handled Diagnosis has obviously been difficult, but careful study of the distribution of the eruption, and the results of agglutination and vaccination tests, have made it clear that, although anomalous the disease is a genuine variety of small-pox A leading feature is that the majority of the patients are children of or under school age, and that they are unvaccinated The

An Electrolytic Solution for Sterilising Wounds.

It will be remembered that remarkable results were obtained during the late war by the use of Carrel-Dakin solution for the treatment of infected wounds Chevrier, of Bordeaux, suggests a method in which for Dakin's solution is substituted a fluid prepared by electrolysis of Ringer-Locke saline The passage of an electric current through this fluid at a temperature of 37° C releases two powerful antiseptics ozone and chlorine, which instantly sterilise (so to speak) the infected tissues. It is hoped that this method may be a means of producing antisepsis without violation of the rigorous laws of physiology.

Tuberculosis and Cancer.

Writing in the *Presse Medicale* recently Arnould points out that there is a tendency to exaggerate the incidence and mortality of cancer. In relation to tuberculosis they appear to have risen, largely because tubercle has been considerably reduced by modern hygienic and sanitary practice. It is very questionable he says, whether cancer has actually increased and the economic loss caused by this disease by no means approaches the loss due to tuberculosis, a statement supported by statistics from Holland Norway, England, France and other countries Scarcely one-fifth of the deaths due to cancer occur during the period of full productivity, whereas four-fifths of the mortality from tuberculosis is at ages when the victims should be at work. Tuberculosis thus costs communities twice as much as cancer.

The Botelho Cancer Reaction.

Roussy and Peyre have examined the Botelho diagnostic test of cancer in 83 cases with the following results With the serum of 52 cancer patients 42 tests were positive and 10 negative With that of 21 non-cancerous patients, 6 tests were positive and 15 negative. With 9 samples of serum obtained from patients with inflammatory and glandular affections, the positive tests numbered 5, the negative 4 The experimenters conclude that the test cannot be depended on for the certain diagnosis of cancer

In the treatment of varicose veins Dr Humbert recommends the simultaneous use of sclerosing injections (chiefly of sodium salicylate) and adhesive bandaging The technique is delicate, and much experience and judgment are required In selecting the substances and concentrations for injection special attention must be paid to the state of the local lesions and the character and peculiarities of the veins

The Third International Congress on Urology will be held at Brussels from August 3rd to 9th The questions on the agenda include the Physico-therapy of Vesical Tumours and the Treatment of Genital Tuberculosis

The Fortieth French Ophthalmological Congress will begin on May 9th. The principal subject will be the relation of the sympathetic nervous system to ocular pathology and especially to intraocular circulation. Information is obtainable from Dr R Onfray, 6 Avenue de la Motte-Picquet Paris

A congress on arthritis will be held at Vittel at Whitsuntide (June 5th and 6th). Particulars may be had from Mr Renard Soc gen des Eaux Vittel, Vosges

MEDICINE AND THE LAW.

Libel Action by an Escaped Asylum Inmate.

An escape from a lunatic asylum has sometimes led to legal proceedings, but can seldom have occasioned a claim so remarkable as that of a plaintiff in a libel action tried lately before Mr Justice Rowlatt and a special jury. The plaintiff's grievance was that a London newspaper had published an article headed 'Madman Free in London ' in which he was described as a dangerous lunatic who had escaped from an asylum: this publication he said was libellous and had prevented him from getting an honest living as a hairdresser. The newspaper's defence was that the article was true in substance and fact and that in so far as the words were matters of comment, they were published in good faith and without malice on a matter of public interest The plaintiff who appeared in person, gave a frank account of his history. He was sentenced in 1919 to five years' penal servitude for shooting at two policemen with intent to do them grievous bodily harm At the time of the offence he and another man were attempting to commit a burglary at Finchley, and he was armed with a pistol a jemmy, and a torch He served part of his sentence at Wandsworth prison part at Parkhurst, and from May, 1920, to August 1924, he was confined at the Broadmoor Criminal Lunatic Asylum On his release he was sent to Napsbury Lunatic Asylum for about 16 months; then his relatives had him removed he said, to Peckham House From the latter institution he escaped on Feb 17th, 1926 and the article of which he complained was published on the following morning. He kept quiet for a fortnight and afterwards tried to get work at his trade as a hairdresser. In one case a hairdresser refused to employ him because he answered the description published in the newspaper. Some of these facts were stated in his evidence in chief others were admitted in the course of cross-examination during which he agreed that while at Broadmoor, he might have been described as "destructive cunning and threatening," though he added that not all the inmates at Broadmoor were insane According to the account of the case in the *Times* among the witnesses whom he called were the secretary of Peckham House (who said he knew nothing against him as a patient) Dr. Hector Munro (who examined him in March, 1926 and certified that he then seemed quite able to look after himself and his affairs and that the examination revealed no trace of mental derangement) and three hairdressers who had employed him since his escape and said they found him sane and peaceable The learned judge told the jury that the plaintiff had evidently been a very dangerous man who had been sentenced for a serious crime and had escaped from an asylum: it was for the jury to say whether the defendant newspaper had done more than it was justified in doing. The jury returned a verdict for the defendants It is something of a relief to record a case of this kind where there was no charge of negligence against a certifying doctor and no conflict of medical evidence.

"Holding-out" by Unregistered Dentist

The stipendiary magistrate at West Ham Police-court imposed last week a fine of £40 upon a prosecution by the Dental Board The summons under Section 1 of the Dentists Act of 1921, alleged that the defendant held himself out as practising or being prepared to practise dentistry in contravention of the Act. Evidence was given that his name was struck off the Dentists' Register on June 1st 1926, the principal ground being an allegation of advertising. Two witnesses testified that on the defendant's window were the words 'Mr. Wm Birkett Dentist.' and that on doors leading into the premises was lettering showing Birkett Dentists Ltd and also Mr Wm Birkett, Dental Practitioner. According to the report of the case in the *Times* four witnesses called for the defence denied that the words were late Dr. John McVail used to emphasise the fact that, in badly vaccinated areas, small-pox began to appear disproportionately amongst the children under 10, as it did in the very early days of the nineteenth century When vaccination became practically universal, the disease was rarely to be met with in children under 10 years old Dundee is repeating the experience now familiar elsewhere The medical officer of health and his local authority have acted with promptitude and vigour, both in extending hospital space and in securing vaccination Some 9 000 children have been vaccinated or re-vaccinated

The Pharmacopœial Preparations of Ergot

A recent meeting of the Edinburgh Obstetrical Society began with a paper by Prof A J Clark on the question whether the pharmacopœial preparations of ergot contain active principles The history of ergot epidemics, he said, showed that ergot taken by mouth produced toxic effects, and the frequency of abortion during epidemics of ergotism had probably led to its use in therapeutics Its outstanding effect in treatment was that, when given by the mouth during labour, it caused increased force and frequency of pains within 20 minutes, the increased action being so powerful as to be dangerous if there was any mechanical obstruction This was an unusually straightforward and easily recognisable therapeutic action, and though the active principles of ergot were unstable, it was remarkable that there should be any doubt whether any given preparation was active or inactive

The chemistry of ergot, he said, had long been a puzzle In 1874, Tanret had isolated the crystalline alkaloid ergotamine This proved to be inert, but in 1906, Barger and Carr had isolated the alkaloid ergotoxin which produced all the typical pharmacological actions of ergot and was found to be the hydrate of ergotinine In 1922 Stoll had isolated another specific alkaloid, ergotamine The pharmacological actions of ergotoxin and ergotamine appeared to be identical In addition to the specific alkaloids, ergot contained a remarkable medley of breakdown products of proteins Of these, tyramine and histamine, the amines derived from the amino-acids tyrosine and histidine, had received most attention These drugs produced remarkable and interesting pharmacological actions when given hypodermically, but had very little action when given by mouth The quantity of them present in ergot was too small to be of any importance when ergot was given orally The therapeutic action of ergot therefore depended entirely on the specific alkaloids, of which it contained 0 1 to 0 2 per cent In 1907, Barger and Dale had pointed out that, since ergotoxin was insoluble in water, the liquid extract of ergot could contain little or none of this active principle In 1913, Carr and Dale had criticised the pharmacopœial preparations in detail, showing that they were all produced in such a way as to lose nearly all the active principles These criticisms were not affected by the discovery of the new alkaloid ergotamine, for this had similar solubilities to those of ergotoxin In 1923, Prof Clark had himself performed a series of tests on pharmacopœial preparations made from ergot of known activity, and had found that the processes of preparation involved the loss of 97 per cent of the active principle, except in the case of the ammoniated tincture in which one quarter of the active principle was retained Most of the foreign pharmacopœias, said Prof Clark, contained rational methods for making ergot preparations Curiously enough each revision of the British Pharmacopœia since 1885 had made the British preparations as a whole worse than they were previously As a new pharmacopœia was likely to be prepared soon, the question was one of obvious practical importance He found it difficult to understand why obstetricians had accepted, and apparently had used without much complaint for 30 years, preparations of ergot which were found to be inert when judged by pharmacological and chemical tests

(FROM OUR OWN CORRESPONDENTS)

The Box System for Babies

THE lives of thousands of French children were saved during the war by the establishment of *chambres d'allaitement* at institutions employing women The best results were obtained at those which were visited every week by a pædiatrist, and an interesting account of the one which serves the personnel of the Salpêtrière Hospital has recently been given by Prof Armand Delille Here the arrangements permit of the isolation of each baby in a kind of box, where it is breast-fed by the mother every three hours During the past four years there has not been a single death from digestive troubles among 200 infants accommodated, and in spite of occasional cases of measles, whooping cough, and diphtheria brought in from outside, there has been no epidemic of these diseases The box system, if in general use at creches, would reduce infantile mortality to a minimum At such institutions it is also possible to adopt prophylactic measures against rickets which is found in about 7 per cent of children throughout France At the Salpêtrière *chambre d'allaitement* the babies are given sun-baths as a routine during fine weather From April to October, whenever there is enough sunlight, they are exposed naked to the rays, their cradles being taken out on a terrace facing south-east Not one of the 194 children thus treated has developed rickets Some of them born in November or December and appearing weakly, had ultra-violet baths during the winter, but those born after the end of January had nothing but ordinary sunshine This is a useful demonstration of the ease with which a serious disease may be prevented by simple measures

Treatment of Asthma

As a treatment for asthma Dr Paul Cantonnet of Paris recommends daily intramuscular injection of 1 to 3 c cm of a fresh 5 per cent solution of iodised polypeptone, made up in hypertonic (1 5 per cent) saline An accessory form of treatment is nasal insufflation of stimulating and astringent powders and intratracheal injections having the same effect on the lower respiratory passages Dr Cantonnet claims that in only 28 cases out of 3200 has there been complete failure Of the remainder, 50 to 75 per cent were cured in 20 to 25 days, and the rest after from one to four relapses As a rule the attacks disappeared during the first ten days, generally in the first five

Benzyl Cinnamic Ether and Pulmonary Tuberculosis

The use of benzyl cinnamic ether in the treatment of tuberculous epididymo-orchitis has already been described in THE LANCET (1926, ii, 824) Dr Jacobson of Paris who devised the method, has reported to the Société Médicale des Hôpitaux on its results in 10 cases of pulmonary tubercle, none of which was suitable for artificial pneumothorax Over a period of 12 days 0 25 c cm of the drug was given to each patient after which there was an interval of 18 days before treatment recommenced It is given as an intramuscular injection in an oily suspension and is well tolerated Of the ten patients, two died some months after administration ceased, in one there was improvement of the general condition without apparent change in the pulmonary lesion whilst in the remaining seven there was distinct amelioration of the general condition and of the physical signs, together with a significant alteration in the radiographic appearances Under the influence of the drug the focus of infection in the lung seemed to undergo sclerosis

Death of Prof Gilbert

Prof Augustin Gilbert, who has died after a short illness, was born in 1858 at Buzancy (Ardennes) and went to school at Rheims At the age of 18 he came to Paris and took up the study of medicine He

PHLEBITIS AND THROMBOPHLEBITIS

To the Editor of THE LANCET

SIR,—Dr. W. Bain's article has once again drawn attention to the prevalence of venous thrombosis following intoxications and infections, and my excuse for entering upon a discussion on the subject is because my research work throws light both upon the cause and the treatment In all intoxications and infections some of the protein particles in the plasma increase in size, or undergo what I term "hydration," to avoid being sent into true solution Once the cause of the dehydration and the consequent hydration has been removed the hydrated particles undergo the cyclical change of dispersion Should the division and subdivision of the protein particles result in an enormous number being formed, the dispersed phase takes the place of the dispersion medium (the liquid portion of the plasma) and vice versa to form a gel The gelation of the protein particles occurs where the circulation is most sluggish—viz, in the veins—to cause what is known as "thrombosis" Although gelation occurs frequently in the veins of the lower extremities, it is particularly apt to occur in the lungs Pulmonary gelation when very marked occurs in the pulmonary artery which functions as a vein, to cause what is erroneously known as "pulmonary embolism" When the gelation is less marked pulmonary œdema is produced a condition which is usually wrongly named "pneumonia" Pulmonary embolus is wrongly named because the thrombus is formed *in situ* Venous thrombosis may occur in more than one vein at a time and the lesion may spread by direct extension, but rarely, if ever, does a portion of the thrombus become dislodged to settle elsewhere Therefore, the long-continued rest generally advised is not necessary, indeed it is actually harmful Another point in this connexion is the fact that early movement, once the intoxicant or infective agent has ceased its activity, would prevent gelation from occurring Pulmonary thrombosis should not be called pneumonia because it is due to a chemico-physical change the protein particles in the plasma undergo and is independent of micro-organisms This rules out of court the idea that the type of venous thrombosis referred to is a septic process

Protein gelation gives a typical blood-picture. The serum is very clear, the suspension stability of the red blood corpuscles is reduced the refractive index of the serum is lowered, the viscosity of the blood is raised, the coagulation time is shortened, the blood is particularly dark, the percentage of one or more of the adsorbed protein constituents is raised (sugar, urea, calcium, &c), and the serum viewed with a dark-ground condenser shows very few particles moving and a carpet of precipitated particles, with or without an extensive fibrin network

Protein gelation differs from intravascular clotting produced by conductors, of which para-thor-mone is a good example, in many respects Intravascular clotting takes place in the arteries, the blood is bright red, the suspension stability of the red blood corpuscles is not reduced, the refractive index of the serum is not lowered, and the serum examined with a dark-ground condenser reveals myriads of particles with active Brownian movements Protein gelation is characterised by the great loss of electricity sustained by the protein particles, hence the reason why the particles coalesce to form a thrombus Therefore the rational treatment is to supply electrons to the particles and the moment their negative charge is increased the agglutinations break up and the particles are restored once more to the circulation When fever is present I prescribe Sup 36 in 0 01 g doses and when there is no fever Sum 468 in 0 002 g doses Sup 36 should be injected intramuscularly on two successive days and again on the fifth day Sum 468 should be injected intramuscularly every day or every other day until the thrombus has vanished I have treated many cases in this way with uniform success and have had all the patients walking about in less than a fortnight.

The phenomenon of clotting is fully described in "The Nature of Disease," (Vol I. Chapter XIV), so I need say no more here than that clotting is not a ferment action, that there are no such substances as prothrombin and thrombin, that clotting can occur independently of blood-platelets, and that calcium has no specific rôle —I am, Sir, yours faithfully,

Wimpole street, W 1, April 2nd, 1927

ANTERIOR SUBLUXATION OF THE ATLAS

To the Editor of THE LANCET.

SIR,—While congratulating Prof Oppel on the brilliance of his technique which enabled him to remove successfully part of the anterior arch of the atlas, may we at the same time draw attention to what appears to be a misconception of the mechanism of the occipito-atlanto-axial articulation In discussing the plan of the operation (THE LANCET, April 2nd, p 700), he says —

> the crux of the intended operation would consist in taking measures to avert the possibility of an ensuing compression of the medulla It thus becomes evident that to gain that purpose the anterior arch of the atlas should be removed This measure alone would permit the detached dens to move forward with the subsequent slipping forward of the atlas

Surely, in the event of the transverse ligament giving way, absence of the anterior arch of the atlas would not prevent compression of the medulla between the posterior arch and the odontoid process Would not such a calamity be more effectively and more easily avoided by a laminectomy of the atlas? It appears to us that, judging from the result, the operation was desirable from the point of view of improving the function of these joints, but we fail to understand how the absence of the anterior arch could avert the possibility of medullary compression, and would suggest that this depended entirely upon the fact that the transverse part of the cruciform ligament remained intact

We are, Sir, yours faithfully,

VENEREAL DISEASE IN THE MEDICAL CURRICULUM.

To the Editor of THE LANCET

SIR,—In the report of my remarks at the recent meeting of the Medical Society for the Study of Venereal Diseases (THE LANCET. April 2nd, p 707) my main contention was omitted This was that the student should attend the surgical out-patient department from even the very beginning of his studentship, if only for an hour a day Under an inspiring and judicious instructor (mine was the well-known Joseph Bell) much lasting clinical knowledge can be acquired long before the full details of anatomy, physiology, and pathology are mastered This is particularly true with regard to the external manifestations of such a disease as syphilis Even though the thorough treatment may be best taught in a special department, its external aspects should be studied in the surgical out-patient department where they can be compared with the various other conditions from which they have to be distinguished An early acquaintance with the features and possibilities of this disease is important for all who may as dressers (or nurses) have to handle lesions which are possibly "specific"

I am, Sir, yours faithfully,

London, April 10th, 1927 JAMES DUNDAS GRANT exhibited as alleged by the prosecution The *defendant himself stated that, since his name had been* erased from the Register he had not used the description of dentist, he said he had put up " Late Dentist " and also " Dental Prosthetician " Asked the meaning of the latter phrase by the magistrate, he said the word meant a dental mechanic and was a common word in the trade Mr Abinger, who appeared for the defendant, said Mr Birkett was the director of a company carrying on business, and that all its dental work was done by registered and qualified men It was suggested that the prosecution was inspired by malice and spite on the part of a rival The magistrate, however imposed a fine as stated, and said he was convinced that the word " practitioner " had been altered to represent a mechanic There had been another summons against Mr Birkett for actually practising dentistry in contravention of the statute but the prosecution withdrew this summons at the outset of the proceedings, and the magistrate allowed the defendant £10 10*s* costs in this respect

The decision in these " holding-out " cases depends upon the facts and the magistrate's view of them The evidence here was conflicting It is conceivable that the words which the defendant stated he had himself used might be proper and harmless in certain circumstances, and that they would raise an inference of " holding-out " in other circumstances Presumably the evidence of the witnesses for the prosecution was accepted

" *Heather Honey* "

Upon a summons recently taken out by the Ministry of Agriculture, the West London Police-court magistrate has held that the label " Heather Honey " is not a mere generic trade description, but that it implies that what is offered for sale does contain heather pollen A company which was responsible for the selling of a jar of honey labelled " Heather Honey," which on analysis was found to contain no trace of heather pollen, was fined £20 The defendants argued that the label was merely descriptive of the type, heavier honey being classified in the category of heather honey, and the higher and finer honey being put in the category of clover honey They argued that the label was not a guarantee that the bees had visited heather, and they pointed out that obviously there could not be any great stock of actual heather-flavoured honey on the market The magistrate said the prosecution had proved its case He was satisfied that there was such a thing as heather honey—i e , honey substantially made from the heather bloom The label implied that the honey did contain heather pollen The decision is of importance to retailers

---

WESTMINSTER OPHTHALMIC HOSPITAL —On April 6th a reception was held at the Westminster City Hall in the interest of the rebuilding fund of Westminster Hospital The Mayor of Westminster, Councillor S P B Bucknill, who received the guests, opened the proceedings with an address in which he explained that the hospital was founded over a century ago by an army surgeon, Mr G J Guthrie, at his own house on the site of the present Berkeley Hotel The hospital was subsequently removed to Marylebone-street and afterwards to Warwick-street, Golden-square and in 1832 the present hospital in King William-street, Strand, was erected Lord Desart, chairman of the rebuilding fund said that the work of the hospital had so increased that it was necessary to seek larger premises The freehold of the site and buildings in King William-street had been realised and a new hospital would be built in Broad-street Shaftesbury avenue, where it would be possible to train more students and more nurses and where the poor would be treated along with the more well-to do and especially the children of all classes, the preservation of whose eyesight was a matter of deep national concern In order that the new hospital might start free of debt a sum of £60,000 was required immediately Mr Bernhard Baron had given £10,000 and other sums had been received from generous donors The architect Mr Percy Adams, F R I B A then presented the plans of the new hospital, after which Mr W H McMullen explained how modern eye surgery was carried out at the hospital Sir Richard Cruise subsequently demonstrated some of the scientific apparatus used there

TESTS FOR DRUNKENNESS

To the Editor of THE LANCET

SIR,—I am happy to be able to assure Dr Southgate that some of the senior police medical officers are far from being satisfied with the present tests for drunkenness and that the great scientific value and possible practical importance of his work and that of Dr Carter is recognised by them He will be glad to hear that active investigations are at present being made with a view to a corroboration of their observations —I am, Sir, yours faithfully,

London, W , April 8th, 1927 MAURICE A CASSIDY.

SPLENECTOMY IN MALARIAL SUBJECTS

To the Editor of THE LANCET

SIR,—With reference to Dr J. MacQueen's interesting account of his successful treatment of an enlarged and ruptured malarial spleen, published in your issue of Feb 26th, in which he invites the experience of others, the following brief summary of the last ten splenectomies performed at the Altounyan Hospital may be of interest

1 Male, aged 25, malarial splenomegaly 1/5/24 Splenectomy Diaphragmatic adhesions 2/5/24 Profound shock. Blood transfusion Death

2 Female, aged 10 Malarial splenomegaly 23/6 24 Blood transfusion 1/7/24 Splenectomy Slight shock Blood transfusion 13/7/24 Discharged convalescent

3 Female, aged 40, malarial splenomegaly 3/7/24 Splenectomy Spleen weighed 9 lb No shock Blood transfusion Discharged convalescent ten days later

4 Male, aged 18, malarial splenomegaly 20/11'24 Splenectomy Blood transfusion No shock Discharged convalescent 15 days later

5 Male aged 20 Splenic anæmia 24/1/25 Splenectomy Blood transfusion No shock 6/2/25 Death from exhaustion

6 Female, aged 30, malarial splenomegaly 28/3/25 Splenectomy Blood transfusion No shock 27/4/25 Discharged convalescent

7 Male, aged 30, malarial splenomegaly 2/6/25 Splenectomy Blood transfusion No shock 4/6/25 Death Cause unknown

8 Female, aged 15, malarial splenomegaly 13/5/26 Splenectomy Blood transfusion Slight shock 26/5/26 Discharged convalescent

9 Female, aged 35, splenomegaly Ascites Cirrhosis of liver 6/11/26 Splenectomy Many adhesions which caused profuse hæmorrhage Blood transfusion on the table Death one hour later

10 Female, aged 20, torsion of the spleen simulating an ovarian cyst 22/12/26 Splenectomy Malarial spleen weighed 4 lb Blood transfusion No shock 3/1/27 Discharged convalescent

I should say that, provided there are no extensive diaphragmatic adhesions, the removal of the malarial spleen need not carry a higher mortality than excision in other diseases Here we are frequently forced to abandon all attempts at splenectomy owing to formidable adhesions Case 9 shows the danger even of exploring such cases Bleeding from adhesions was started by the exploring fingers and could not be arrested until the spleen had been removed , the pedicle was too short to clamp before delivery of the spleen As to the late effects we have as yet no evidence that the procedure is of lasting benefit to the malarial patient

With regard to the rupture of the diaphragm reported by Dr MacQueen, I suggest that it is difficult to diagnose this condition without actually seeing the lesion I have been more than once misled by the innocent sucking in of air into the subdiaphragmatic pouch

I am, Sir, yours faithfully,
E H R ALTOUNYAN M D Camb
The Altounyan Hospital, Aleppo, Syria

Obituary.

JOHN ERNEST HODDER-WILLIAMS, C.V.O.,

CHAIRMAN OF THE LANCET

WE deeply regret to announce the death, which occurred on Friday last, April 8th, of Sir Ernest Hodder-Williams, head of the publishing firm of Hodder and Stoughton, and for rather more than six years Chairman of Messrs. Wakley and Sons, the proprietors of THE LANCET.

John Ernest Hodder-Williams was the eldest son of John Williams of Bromley by Mary Hodder, who was the daughter of Matthew Hodder, the famous publisher who, in association with Thomas Wilberforce Stoughton, developed the activities of the House later known by their joint names.

ERNEST HODDER-WILLIAMS.

Ernest Williams was educated at the City of London School and University College, London, and further pursued his studies in Paris and Berlin. He entered the firm of Hodder and Stoughton when little more than a boy, and consequently worked for more than fifteen years under his grandfather, who did not die until 1911, after 60 unbroken years as a publisher. On Matthew Hodder's death, T. W. Stoughton, who had been connected with the firm for over 40 years, with the late Sir William Robertson Nicoll, as literary adviser, became the senior partner; and upon his death in 1917 Ernest Hodder-Williams—the family having added the grandfather's name to their own—became the head of the firm. The progress of the firm during the association with it of Ernest Hodder-Williams and his brothers has been remarkable. Expansion in all directions of publishing activity was associated also with the success of the well-known newspapers the *British Weekly* and the *Bookman*, both of which are the property of the firm. The early bent of the House towards religious publication was never lost, but aided by far-reaching views, and with assiduous conduct of affairs, the list of publications rapidly became of an extraordinarily comprehensive nature, and now their imprint will be found upon standard works under every heading in any catalogue.

In 1920 the controlling powers of the Company owning THE LANCET were purchased by Messrs. Hodder and Stoughton and Sir Ernest Hodder-Williams became Chairman of the Board, and we may quote, as descriptive of his relations with THE LANCET, his own words spoken at the centenary dinner of the paper. "I am very proud," he said, "to stand to-night in this place of a great tradition. Perhaps, under the circumstances, you will allow one personal reminiscence. In the days of my early manhood—and my father, whom I am delighted to see here this evening, will bear me out when I say that at that time one reached early manhood very early—I had the ambition to enter the medical profession, but the Fates, no doubt in kindness to my future patients, decided entirely otherwise. They did not, however, altogether forget, and after many years they presented to me a grand old surgical instrument—THE LANCET—fashioned out of a material with which I had become somewhat acquainted. And when I use the personal pronoun may I say at once that I refer not only to myself but to all my splendid associates. As proprietors of THE LANCET, my brothers and I made a vow—we have tried to keep it—that we would, as far as in us lay, do nothing which might leave the slightest stain of dishonour on a most highly honoured name. In these latter years laymen, business men and business women have worked increasingly side by side with professional men and professional women in many fields of service of peace and of war; in none, I think, with greater honour to themselves and to their cause than in the field of healing. It is because of this that we business men who control the destiny of THE LANCET feel deeply our responsibilities, our privilege and our opportunity. If we can be of any service in scattering far and wide the fine grain garnered from medical knowledge and experience we shall have share in the joy of the reaping."

In addition to his publishing work and his interest in this paper, Sir Ernest Hodder-Williams was intimately and importantly connected with the affairs of the City of London. He was for a long period a member of the Corporation, and during the past eight years had been Chairman of the County Purposes Committee. Further he had a deep and hereditary concern in the prosperity of the Young Men's Christian Association. His father was a nephew and intimate friend of Sir George Williams, the founder of the Y.M.C.A., whose right-hand companion in the first developments of the movement had been the veteran Matthew Hodder. In 1906 he wrote the life of Sir George Williams, in which the initiation, early struggles

"THE LONDON CLINIC"

To the Editor of The Lancet

Sir,—In view of certain publicity which has recently been given to the London Clinic (founded and maintained by the British Humane Association), we, the undersigned, wish it to be known that we have severed our connexion with that body

INFLUENZA A PERSONAL STORY

To the Editor of The Lancet.

Sir,—During a recent attack of pure influenza I reflected upon the field of action of the germs, or of their conflict with phagocytes The influenza was "pure" inasmuch as none of the germs which are usually loafing about the throat took part in the frolic After breakfast I had done my chores in the garden (my gardener is free on Sunday), and returned to the house without an inkling of impending trouble There was absolutely no symptoms, yet unwonted disinclination to starting for church aroused suspicion Temperature 100 6° F Later in the day the raised temperature caused the epithelium of the throat the secrete clean white mucus, which provoked a cough For three days I put nothing into my stomach but water and carbonate of soda, this in my personal experience being the only means of avoiding the misery of flatulent distension which results from taking food when the digestive secretions are in abeyance, and a high temperature favours fermentation It was clear that the skin, muscles, and interstitial lymphatic tissue were not affected During this period and the succeeding two days the clear urine was the colour of dark brown sherry Destruction of blood pigment was going on The liver was certainly within the field of operations No food and a motion every day had emptied the lower bowel before, on the fifth morning, I passed a very large quantity of black inspissated bile, which had collected in the sacculi of the colon The hæmolytic capacity of the germ may possibly afford a clue to its identity. Until I discovered that I was feverish I was head to head with members of my family; but they escaped This seems to show that in the earliest stage of influenza germs do not escape into the breath

I am, Sir, yours faithfully,

April 7th, 1927 Alex Hill.

GLYCOSURIA COMPLICATED BY GALL-STONES

To the Editor of The Lancet

Sir,—In connexion with the case described by Dr Shapland in your last issue, may I point out that, in my experience, an abnormally low threshold for glucose is not uncommon in diabetes The systematic chemical analysis of the whole blood made in all my cases has shown that, as a rule, this lowering of the threshold is associated with a subnormal percentage of calcium upon which it appears to depend, for the threshold rises if the percentage of calcium increases Partial exhaustion of the parathyroids as a result of chronic toxæmia appears to be the most common cause, but, since disturbances of calcium metabolism occur in connexion with inflammatory affections of the pancreas, as I believe I was the first to point out in 1904, it may also arise as a consequence of chronic pancreatitis The latter may be the explanation of the low threshold in Dr Shapland's case

It has long been recognised that glycosuria is a relatively uncommon result of the chronic interstitial pancreatitis associated with gall-stones and that when it occurs it is of a mild type But the disease is usually progressive and, although operative interference may bring about an improvement in the patient's carbohydrate tolerance, it is often only temporary and frank diabetes ultimately develops I have several patients in whom this series of events, spread over as long as ten years in one instance, has taken place and they are now being kept alive only by the use of considerable doses of insulin While, therefore, I agree with Dr Shapland that removal of the diseased gall-bladder in his case was probably the deciding factor in the alleviation of the diabetic condition, I should be doubtful whether the recovery will be permanent

I am, Sir, yours faithfully,

P J Cammidge.

Nottingham-place, W, April 9th, 1927

THE GLUT IN WOMEN DOCTORS

To the Editor of The Lancet

Sir,—The glut in women doctors still continues A single advertisement inserted in a London weekly medical journal produced 48 applicants for two posts—viz, those of senior and junior resident medical officers to a children's hospital in the North of England, the salaries being £120 and £100. Recently a like advertisement brought forth only 12 male candidates for the post of house physician at our general hospital

None of the former applicants gave her age as over 29 Thirty-eight of the candidates had held previous hospital appointments lasting from 2 to 50 months Many had gone from post to post All the applicants were University graduates except one, who held the diploma of the London Conjoint College and she is a R.M O, in a homœopathic hospital Twenty-three had English qualifications, 21 Scottish, and 4 Irish (one from north Ireland and 3 from the Free State) The 23 English women had degress from Oxford 1, Durham 4, London 10 (University 9, Conjoint Colleges 1), Birmingham 1, Liverpool 3, and Manchester 4 The 21 Scottish graduates were 3 from St Andrews, 6 from Edinburgh, 8 from Glasgow, and 4 from Aberdeen The Irish graduates were 1 from Belfast and 3 from Dublin The large number of Scottish applicants were out of proportion to the numbers qualifying across the border Of over 2000 new names added to the Medical Register last year from Great Britain, two thirds were from England and one-third from Scotland, although Scotland has only one-seventh the population of England The Oxford graduate was appointed senior and a Durham graduate, who had local influence, junior medical officer

With regard to the excessive number of graduates (men and women) entering the profession in the face of a fallen and still falling sickness rate—the Medical Register already contains over 53,000 names—it is said that out of every three qualifying in Ireland two must emigrate, and the proportion must be higher from Scotland The celebrated Abernethy at the first meeting of his annual class of medical students used to exclaim, "Good God, gentlemen, what will become of you all?" So we may say to-day. Some of the best American Universities (Pennsylvania, Baltimore, &c.), restrict their medical students to a fixed number, which can be adequately taught the practical side of their work, some of them admitting less than a quarter of the applicants and selecting only the best after inquiry and examination

I am, Sir, yours faithfully,

Sunderland, April 7th 1927 Wm Robinson

defect—viz, rheumatic fever, 2 , chorea, 8 , chorea and rheumatic fever, 2 , chorea and subacute rheumatism, 6 , and subacute rheumatism, 9 There are 13,008 children on the rolls of the Reading elementary schools so that the 57 known " cardiacs " would be equivalent to 4 4 per 1000 of the school population, and the 84 " cardiacs " and " rheumatics " combined to 6 5 per 1000 Dr Milligan does not think they have been successful in tracing all the cases of rheumatic and allied conditions in the schools

Barnstaple

The statistics for 1926 of this rural district are as follow —

Population—18,630 ; Birth-rate 16 1 ; Death-rates per 1000 of the population All causes 10 8 , Tubercle 0 75 , Cancer 1 4 , Respiratory diseases with Influenza 1 0 , Heart disease 1 4 Death-rates per 1000 births Infants 49 5 , Mothers from childbirth 0 0

Dr John R Harper says his large district (its area is 129,768 acres) is almost entirely agricultural, except for a few parishes on the coast where there is fishing The standard of living and comfort for labourers has improved during recent years, but much remains to be done in the replacement of " picturesque but *badly lighted and ill-ventilated cottages* " The population is largely increased by visitors during the summer months, and the popularity of Croyde has rendered the sewage disposal question acute The sanitary inspectors mention that the increasing use of tinned and bottled foods makes it essential for each parish council to arrange for a recognised dumping place At present the hedges, rivers, streams and beaches near any hamlet give evidence of this need The building trade has been active and more plans were deposited in 1926 than in any of the last 25 years The 92 dwelling-houses included 23 bungalows in brick or stone, 22 wood and asbestos bungalows, and 47 brick or stone houses of two or more storeys

---

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 2ND, 1927

Notifications—The following cases of infectious disease were notified during the week —Small-pox, 392 (last week 404) , scarlet fever, 1311 , diphtheria, 909 , enteric fever, 39 ; pneumonia 1264 , puerperal fever, 29 , puerperal pyrexia, 98 , cerebro-spinal fever, 8 , acute poliomyelitis, 8 , acute polio-encephalitis, 1 , encephalitis lethargica, 36 , dysentery, 2 , ophthalmia neonatorum, 133 No case of cholera, plague or typhus fever was notified during the week

Outside the counties in which small-pox has recently been prevalent, one case was reported from each of the counties of Kent (Gravesend) and Surrey (Wimbledon) We learn from Dr J Cates that the case of small-pox at present under treatment in Surrey is of the severe variety met with in India Infection occurred on a P & O boat The attack of the disease is moderately mild and the patient is doing well

Deaths—In the aggregate of great towns including London there was no death from small-pox, 2 (0) from enteric fever, 79 (3), from measles, 5 (1), from scarlet fever, 70 (22), from whooping-cough, 25 (5), from diphtheria, 40 (9) from diarrhœa and enteritis under two years, and 160 (25) from influenza The figures in parentheses are those for London itself

---

DONATIONS AND BEQUESTS—St Peter's Hospital for Stone and other Urinary Diseases has received an anonymous gift of £5000—Mr James Talbot, Birmingham, left £500 each to Queen's Hospital, Birmingham, Birmingham General Hospital, The China Inland Mission, St Luke's Cottage Homes, the Children's Hospital, Birmingham, and four other institutions, and £250 to Muller's Orphanage—Mr Henry Barry Blagrave, Reading, Berks, left £2000 to the Royal Berks Hospital—Sir Thomas Rodgerson Marsden, Rhos on Sea, and late of Oldham bequeathed £1000 to Oldham Royal Infirmary " if not given in his lifetime "—Sir William Forest, Mayor of Blackburn, has received an anonymous gift of £1000 to the Blackburn War Memorial Infirmary Wing

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND—At a quarterly meeting of the Council held on April 7th Sir Berkeley Moynihan, the President, in the chair, the following were admitted honorary Fellows of the College Roberto Alessandri (Rome), Edward William Archibald (Montreal), Frans Ali Bruno Krogius (Helsingfors), Paul Lecène (Paris), René Leriche (Strasbourg), Rudolph Matas (New Orleans), and Charles Willems (Liège)

The following were elected Fellows of the College as members of 20 years' standing Cecil Fowler Beadles and Sir Henry John Gauvain

E Miles Atkinson, F R C S (Bath), was awarded the Jacksonian Prize for a dissertation on The Pathology, Diagnosis and Treatment of Abscess of the Brain The subject for the year 1928 is the Surgical Treatment of Pulmonary Tuberculosis Herbert Cecil Malleson, M R C S , L D S , was awarded the John Tomes Prize for 1924–26 for work in connexion with Histology and Pathology of the Dental Tissue Robert Gordon Wilbond, of Bristol, who obtained the highest number of marks in Anatomy in the recent First Professional Examination, was appointed a Begley Student for a period of three years The diploma of Fellow was conferred upon G F G Batchelor, St Andrews Univ and Guy's Hosp and *R W Jones, Liverpool Univ* *The Licence in* Dental Surgery was conferred upon S D Marcus, Guy's Hosp

UNIVERSITY OF DURHAM *College of Medicine*—A third lecture on the History of Medicine will be given at the College, Newcastle-upon-Tyne, on Wednesday, April 20th, at 4 45 P M , by Dr Charles Singer, of University College, London Medical practitioners are invited to attend

ROYAL INSTITUTION—On Friday, May 13th, at 9 P M., Sir Humphry Rolleston will give an address entitled Concerning Old Age

QUEEN'S UNIVERSITY CLUB, LONDON—The annual spring dinner of this Club will be held at the Connaught Rooms on Thursday, April 21st, at 7 30 P M. for 8 P M , Prof. J A. Lindsay, the President, in the chair Particulars may be obtained from the Hon Secretaries, Dr Purdon Martin, 9, Harley-street, W 1, and Dr Ivan Magill, 11, Wimpole-street, W.1

ROYAL INSTITUTE OF PUBLIC HEALTH—The Council of the Institute have made the Smith Award to Brevet-Colonel James Robert Kaye, county medical officer of health for the West Riding District of Yorkshire This award, which consists of a bronze figure of Hygeia by Charles L Hartwell, R A., is awarded triennially to a medical officer of health who is recognised as having done the most noteworthy work in the discharge of his official duties

ROYAL SOCIETY OF ARTS—On Monday, April 25th, at 8 P M., Mr John W T Walsh, senior assistant, National Physical Laboratory will give the first of three lectures on the Measurement of Light The other two will be delivered at the same hour on May 2nd and 9th On Wednesday, May 18th, at 8 P M , Mr Robert R Hyde will lecture on Industrial Welfare in Great Britain and the United States

ROYAL SOCIETY OF MEDICINE—A Colyer Prize was founded in June, 1926, to commemorate the 25 years' service of Sir Frank Colyer as honorary curator of the odontological museum Its value is about £20 and it will be awarded triennially for the best original work in dental science completed during the previous five years by a dental surgeon educated at any duly recognised dental school in Great Britain or Northern Ireland who has not been qualified to practise more than five years at the date of the award Applications for the first award should be submitted not later than July 1st, 1928, together with a general account of the candidate's research

THE LATE DR F W APTHORP—Dr Frederick William Apthorp, who recently died at Hove at the age of 78, was a Yorkshireman by birth, and studied medicine at Guy's Hospital, becoming M.R.C S Eng in 1878 The Zulu War broke out soon after he qualified, and he went out to Zululand, serving in the Rorkes Drift area and elsewhere Returning home he was for a time clinical assistant at the Evelina Hospital for Children, and at the Hospital for Disorders of Women in Soho-square He eventually settled at Sidlesham, near Chichester, where in the western division of Sussex he had an extensive practice and held a number of appointments In the early 'nineties he left West Sussex for Burgess Hill, and here he practised until failing health necessitated his retirement in 1921, when over six hundred people subscribed to a testimonial fund Dr Apthorp married in 1897 a daughter of Captain Mailing, C M G , of Hove, and she survives him and great success of the Association were eloquently detailed He was also the author, with Mr. E. C. Vivian, of "The Way of the Red Cross" to which Queen Alexandra contributed a preface, and in which he was able to write with authority, for during the war he superintended for the Government the Red Cross propaganda In all these multifarious activities, and in the assistance of many philanthropic agencies, such as the Royal Female Orphanage at Beddington, he showed the same strenuous enthusiasm and close attention to detail, and there is no doubt that his death, at the early age of 50, was largely due to the perpetual strain to which he subjected a delicate organisation He had a serious breakdown over three months ago, from which he never rallied, and died of heart failure

Sir Ernest Hodder-Williams was knighted in 1919 in respect of his war services, and three years later was created C V.O , being also decorated by the Italian and Belgian Governments He was twice married, first to the daughter of Mr J G Oddy, who died in 1918, and secondly to Lilian, the daughter of Mr J. R Pakeman who survives him. The funeral service was held on Tuesday, April 12th, at the Westminster Chapel, where the Rev Dr J A Hutton spoke to a crowded audience, showing that the mystery of death at the prime of a full and useful life could only be made clear by Christian Faith and the realisation of Christian ideals A memorial service was also held the same day at Christ Church, Grey Friars, in the City The funeral took place privately.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Reading.

Reading is the first county borough to send us a report for 1926, and the following are some of the statistics —

Mid-year population—93,090 , Birth-rate 17 6 , Death-rates per 1000 of the population: All causes 12 2 , Tubercle 1·12 , Cancer 1 54 , Respiratory diseases with Influenza 1 9 , Heart disease 1 5 Death-rates per 1000 births Neo-natal, 24 , Infants 50 , Mothers from childbirth 3 0

Dr H J Milligan explains that the apparent decrease in population since 1925 is due to the fact that the Registrar-General has, in making his estimates, taken into account for the first time the electoral rolls throughout the country The inference from these is that Reading loses population by migration The death-rate from all causes, when standardised for sex and age constitution of the population becomes 10 6 The infant mortality is the lowest recorded, and it becomes more and more a neonatal matter Thus of 83 infant deaths, 24 occurred in the first week and 40 in the first 4 weeks The infant deaths from bronchitis and pneumonia are only about half, and from gastro-intestinal diseases less than one quarter of what they were in the years 1905–8 There is also the satisfaction that the survivors reach school in better physical condition, and that the school report shows that many of the entrants have already undergone remedial treatment—e g , for tonsils and adenoids

The post-war incidence of tuberculosis shows no tendency to decrease , the notifications of pulmonary tuberculosis in 1926 were the highest since 1918, and the deaths were only exceeded by one in the worst year, 1923 There is also no tendency for non-pulmonary forms to decline Two new pavilions have been added to the Park Hospital, and it is hoped to provide there accommodation for advanced female consumptives, as has already been done for men Dr Milligan mentions the very high percentage of tuberculous milks as a "disquieting feature" Out of 42 samples of milk, taken at random, 8 gave a positive result, equivalent to 17 per cent Last year the percentage was 14 In two of the cases the offending animal was not tracked out, probably owing to sales from the milk herd In any case, as Dr Milligan points out, this following-up after sampling is a long and tedious method of eliminating infected animals and a more efficient plan would be constant veterinary supervision and testing of herds The efforts of the National Institute for Research in Dairying keep up interest in this matter in the Reading district, and one licence for the production and sale of "Certified" milk and eleven for the sale of "Grade A (tuberculin-tested)" milk were issued in the Borough during the year There were no licences issued for Grade "A" or "pasteurised" milk, although a considerable proportion of the milk goes through some form of pasteurisation There were two prosecutions of milk vendors for bottling milk in the street

The improvements to the Maternity Home are nearing completion, and the new maternity department for complicated cases of labour at the Royal Berkshire Hospital, with one 5-bed ward and two single-bed wards, was opened during the year Midwives sent for medical aid in 20 per cent of the cases which they attended The new regulation issued by the Ministry, requiring the notification of a rise of temperature of 100 4° F for 24 hours or recurring within 24 hours, in parturient women came into force in October The Local Authority is also required to provide specialist services, if needed Four of the nine cases of puerperal fever ended fatally , three of them were in poor health before the onset of labour The nine cases of pyrexia notified under the new regulations all made good recoveries only three were seriously ill, two suffering from pelvic cellulitis and one from breast abscess Small-pox has not occurred in Reading for 20 years, but the hospital provision at the Whitley camp is quite unsuitable and inadequate, and only 20 per cent of the infants born are now successfully vaccinated The attendances at the infant welfare centres continue to increase Suitable foods are sold at cost price, but that this is not the primary attraction for attendance, says Dr. Milligan, is shown by the fact that two thirds of the infants brought to the centres are breast-fed

The number of new houses erected was 522, the highest since 1905 Of the total 173 were municipal, 231 received a subsidy, and 113 were the result of unaided private enterprise Nevertheless the shortage of working-class houses remains acute and, in the absence of alternative accommodation, slums and overcrowding cannot be tackled Eight small houses in ruinous condition, which should have disappeared long ago, were demolished during the year.

The activated sludge method of sewage disposal has now been in operation for a year, "but the results," Dr Milligan writes, "leave something to be desired By arrangement with the Company alterations are now being carried out in the design of the plant which it is hoped will effect the desired improvement in the character of the effluent"

In his school Report Dr Milligan says "when the results are compared over a period of years it will be found that there is a small but definite improvement in the physical condition of the children examined" The increases in height and weight are shown in tables, and a decrease is noted in the incidence of impetigo, ringworm, unclean heads and conditions accompanying neglect and malnutrition Thirteen out of 14 cases of otorrhœa selected during the year for ionisation "can at present be regarded as cured" The single dentist, Miss Mackinnon, is unable to overtake the whole of the work included in the model scheme of the Board of Education

The number of cases of known organic cardiac disease in the elementary school is 57 (boys 21, girls 36), classified as follows Associated with chorea, 6 , with acute and subacute rheumatism, 27 ; with pneumonia, 2 ; with severe measles and whooping-cough, 2 , with severe scarlet fever, 3 ; with no history of severe illness, 17 There were also found 27 rheumatic conditions with no apparent heart other class of person when it came to assessing Probate Duty, and other things, and on the passing of a practice from one person to another. They could not conceive a goodwill without having on their mind an attachment to a particular site. Take the case of a professional man in Harley-street. A man might wander along Harley-street and knock at a door not feeling quite sure who was behind the door, but he went there because the doctors in that street have a particular reputation. It was the fact that they practised in Harley-street which endowed them with the thing which was called goodwill. Therefore he contended that the site had a great relationship with goodwill and a greater relationship than was conceded in this Bill

Mr. ELLIS DAVIES said that the Bill was disappointing It did not quite carry out the promise made in the King s Speech; certainly it did not fulfil the hopes raised in that speech. It did not enable a lessee. for instance, to claim the enfranchisement of his property; it did not affect a building lease · and it did not affect the houses of professional men. He did not understand why, for instance. a doctor was not to have the right to claim goodwill in respect of the premises which he occupied.

Dr LITTLE said he wished to urge that the provisions of the Bill should apply to the premises occupied by professional men, and especially to doctors' premises There were two classes of doctors who were concerned. First, there were the consultants who were particularly resident in London and largely centred in one part—namely, the division which returned to Parliament, Sir D HOGG, the Attorney-General. He (Dr. LITTLE) hoped that the right hon. gentleman might recognise that a very large body of his constituents were disturbed by the proposals. The way in which the present law acted he might perhaps illustrate by giving the case of a surgeon who took a house for a short period who established a great reputation and at the end of 14 years they might suppose, was faced with the necessity either of removal or of renewing the lease. The landlord understood perfectly well that it was a very damaging thing for the man to remove from the neighbourhood and the lease immediately went up to an extortionate value. This Bill was going to increase that problem very much. Leases were going to be more difficult to obtain under the provisions of this Bill, unless it was made to apply to professional premises The Inland Revenue authorities regarded a doctor's house as business premises, and it seemed very unfair to exclude such houses from this Bill. Another class. perhaps more hardly hit, was the general medical practitioner He had before him a copy of a resolution which contained the plea of the general practitioner. The resolution read:—

> "That this meeting of . . . . . General Medical Practitioners urges the Government to make provision in the new Leasehold Reform Bill for security of holding for general practitioners who have been in many instances compelled to build on leasehold premises in order to comply with the requirements of the National Health Insurance Act with regard to waiting-room accommodation, &c., and to prevent ground landlords acquiring without compensation the goodwill of the practice which they have had no part or lot in creating.'

Members of the medical profession were too busy to take much part in politics. They were a silent profession, and in gratitude for their habitual self-effacement the Home Secretary ought to extend the provisions of this Bill to professional men.

Sir T. INSKIP (Solicitor-General). replying to the debate, said that such points as those raised by Dr LITTLE and others in regard to the goodwill attaching to premises occupied by doctors and professional men generally, were really Committee points. He could assure the House that the Government had not the least desire to reject any reasonable proposals for making the Bill more effective for dealing with those evils which most hon. Members recognised to exist in the working of the leasehold system.

On a division the amendment was rejected by 240 votes to 83 and the Bill was read a second time and committed to a Standing Committee.

THE BUDGET STATEMENT.

Mr CHURCHILL (Chancellor of the Exchequer), in the course of his annual Budget statement in the House of Commons on Monday, April 11th, said that as a result of the general strike and the coal dispute in 1926 there had been a decrease of revenue of over £17,500 000, and on the other hand an increase of expenditure of £14,000,000 This meant a total loss to the Exchequer of about £32,000,000. This was the overwhelming cause of the deficit of £36,500,000 on the Budget of 1926, and of a prospective loss in 1927 of £18,000,000. It further involved losses in 1928 and 1929 amounting to about £2,000,000 In spite of this, however, the revenue had survived. The exchange had stood like a rock without a higher Bank Rate than 5 per cent. with a reserve of gold larger than this time last year. and without any need to touch the precautionary American credits. These had never been used, and on the expiring of the original term next month they would not be renewed. The consuming power of the masses had been little affected by the troubles of last year. Beer and spirits alone among the main items of indirect taxation had reflected the results of the struggle. Income-tax, after deducting losses and deferments due to the strike. was £12,000,000 less than the estimate Estate duty and super-tax together showed an increase of £2,750,000. Sundry loans and miscellaneous revenue had exceeded the estimate by £8,500,000 In the total result the revenue, apart from the strike, was only £1.250,000 below the estimate; and with the strike it was £19,000,000 below the estimate. The expenditure had exceeded the Budget estimate last year by nearly £22,000,000 Of this £15·4 millions were on Consolidated Fund Services—almost entirely debt interest; £6 4 was on Supply Services, and £14,000,000 was due to the coal stoppage The Revenue and Expenditure of 1926 showed a deficit of £36,500,000 on the basis of a £60,000 000 Sinking Fund, instead of an estimated surplus of over £4,000 000 The total estimated expenditure for 1927 was £818,390,000. Referring to the efforts of the Government to reduce expenditure, Mr Churchill announced that during the present financial year the Ministry of Transport would be abolished, retaining the Road Department, the functions of the Ministry of Mines would be distributed to other departments: and the separate existence of the Overseas Trade Department would be terminated. Legislation would be required for this purpose. The extension of the Old Age Pensions to persons of 65 next January would involve a substantial increase in the Ministry of Health. Nevertheless it was proposed to make a marked contraction on new entries into the Civil Service. But this would not mean in itself any large diminution of expenditure. It would be necessary to secure definite reductions in expenditure, and assuming that the economies effected amounted to £8,500,000 the expenditure in 1928 would be the lowest of any year since the war. The further changes proposed in regard to income-tax were as follows. Schedule E (salaries) to be transferred to the basis of the preceding year. Super-tax in future to be assigned to the year prior to the one in which it is paid. This did not affect the basis on which it was assessed, nor the rate of charge nor date of payment, But income-tax and super-tax would be expressed in the form of a single graduated tax on income. A single annual return would be required on the basis of the taxpayer's total income for the preceding year It was also proposed to ask a body of experts to take in hand the codification of the income-tax law Small amendments would be made to prevent avoidance in connexion with subscriptions to charities and to give exemption from income-tax to profits of public schools and other similar trading profits of charities. There would be a reversion to the pre-1918 practice of collecting income-tax on Schedule A in one instalment payable on Jan. 1st. The new sources of revenue to meet the £35,000,000 to £40,000 000 required included a duty on table ware of translucent and vitrified pottery: the inclusion of imported motor tyres under the McKenna duties: a raising of the duty on matches; increases in the duties on wines and tobacco: the transfer of £12 000 000 from the Road Fund to the general funds of the State; and the reduction of the period of credit to brewers.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 6TH.

Small-pox in Dundee.

Mr THOMAS JOHNSTON asked the Secretary of State for Scotland whether he could give the house any further information regarding the outbreak of small-pox in Dundee; and whether he was aware that on the steamer *Macharda*, just arrived at the mouth of the Tay with a cargo of jute from Calcutta. there were three small-pox cases: and what steps he proposed to take to assist the local health authority in protecting the citizens from this additional possible source of infection.—Sir JOHN GILMOUR replied: Up to this morning the number of cases of small-pox diagnosed in Dundee was 66 excluding the three cases on the steamer *Macharda*. Of these. 66 cases 60 have been removed to hospital. The remaining six were not discovered till after recovery, when they were removed to a reception house for observation. Sufficient lymph has been issued for 30,000 vaccinations. A total of 8500 school-children had been vaccinated up to yesterday. The medical officer of health of Dundee received a wireless message and notified my department of the three cases on the steamer *Macharda* before the vessel arrived in port. The duty of dealing with the present situation in *Dundee* rests primarily on the local authority, but the medical officers of the Scottish Board of Health are in close coöperation with the Public Health Department of the *City* and are rendering every assistance in their power The three cases on the *Macharda* provisionally diagnosed as small-pox were removed to hospital immediately on arrival on the afternoon of April 4th, and are very mild in

The marriage took place recently at St John's Church, Stanmore, of Thomas Leslie Wakley, only son of the late Thomas Wakley, L R C P , to Daisy Victoria Trist, eldest daughter of Mr Ronald Trist of Aylward's Chase, Stanmore The interest of the event for readers of The Lancet lies in the fact that Mr T L Wakley, the son of the late Editor of The Lancet, is grandson of Thomas Henry Wakley, for many years Editor of this paper, and great grandson of Thomas Wakley, M P , the founder

Dickinson Research Travelling Scholarship —Applications are invited for this scholarship, which is of the value of £300, for one year, and is open to recent medical graduates of the University of Manchester Particulars will be found in our advertisement columns

British Institute of Philosophical Studies —A course of six lectures on the Philosophy of Religion will be given by Dean Inge at 5 45 P M. on Thursdays, May 12th, 19th, and 26th, and June 2nd, 9th and 16th, at the Royal Society of Arts, 18, John-street, Adelphi, W C 2 (Fee 12*s* 6*d* Members half fee) Applications may be made to the Director of Studies, 88, Kingsway, London, W C 2

Jerusalem Ophthalmic Hospital —The report for 1926 of the Ophthalmic Hospital, maintained at Jerusalem by the Grand Priory in the British Realm of the Order of St John of Jerusalem, states that 18,127 patients, Moslems, Christians and Jews, were treated, and that there were 4234 operations In the six ophthalmic clinics in the rest of Palestine, at Nablus, Tulkeram, and Acre in the north, and Ramleh, Gaza, and Beersheba in the south, conducted by the Government and staffed with nurses trained, paid and supervised by the Order, there were, during the year, 13,576 new patients, 114,392 consultations, and 2684 operations

Auxiliary R A M C Funds —The annual meeting of the members of the Auxiliary Royal Army Medical Corps Funds will be held at 2 30 P M. on Friday, April 29th, at 11, Chandos street, Cavendish-square, W 1, when the annual report and financial statement for 1926 will be presented, and the officers and committee for the current year elected

First Aid for Injured Motorists —The service of first aid in case of motoring accidents organised by the Order of St John and the British Red Cross is now coming into operation The scheme centres upon the 400 ambulance stations which have been established throughout the country since the war First-aid posts are being formed from five to eight miles apart to link up the main ambulance stations These posts will be manned by trained workers and equipped with stretchers and first-aid appliances

New Nurses' Home at Kingston-upon-Thames —The foundation-stone was laid last week of a new nurses home and other additions to the Kingston and District Poor-law Hospital which is a recognised training institute for nurses The buildings, which have been designed by Mr F Danby Smith will have four floors with provision for a fifth when required, and the estimated cost of the scheme is about £100,000 There will be separate bedrooms for 100 nurses and five sisters, suites for four assistant matrons, a library, lecture-room, and sitting-room

Fellowship of Medicine and Post-Graduate Medical Association —The Fellowship has arranged various special courses for May Clinical and cystoscopic demonstrations will be given at the All Saints' Hospital from May 2nd to 28th and at 2 P M on every Wednesday during the four weeks there will be a special lecture on genito-urinary diseases From May 2nd for four weeks, an afternoon course on Psychological Medicine will be held at the Maudsley Hospital Another four weeks' course starting on May 2nd is one on Venereal Diseases at the London Lock Hospital At 5 P M on successive Wednesdays, from May 4th to 25th Prof Louise McIlroy will give lecture-demonstrations on antenatal diagnosis and treatment at the Royal Free Hospital An intensive course will be given at the Central London Throat, Nose and Ear Hospital from May 9th to 28th A clinical and an operative course is undertaken , they may be taken either together or separately, but early application is desirable as entry for the operative course is limited The National Hospital, Queen-square, will give a course on Diseases of the Nervous System, from May 9th to July 15th It will consist of clinical lectures and demonstrations, teaching in the out-patient department, and pathological lectures and demonstrations If there are enough entries courses will also be given on the Anatomy and Physiology of the Nervous System, and on methods of examination Two other courses lasting two weeks, begin on May 16th, at the Infants Hospital and at the Hampstead General Hospital The first is open to those interested in infant welfare work as well as to post-graduates, and the latter is primarily for the benefit of the general practitioner Copies of all syllabuses of the general course programme and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W 1

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Landlord and Tenant Bill.

On Thursday, April 7th, Sir W Joynson-Hicks (Home Secretary), in moving the second reading of the Landlord and Tenant (No 2) Bill, said that under the existing law restrictions were imposed by landlords on the development and improvement of leasehold property which, in this twentieth century, the Government thought should not be imposed There were, in many leases, covenants forbidding structural alterations without the consent of the landlord The landlord retained a power of veto over these alterations There was no tribunal to which the tenant could appeal There was, further, the power of the landlord to take a fine from the lessee before permitting improvements to be made, and also to exact an additional rent It was not proposed by this Bill to take away all these powers, but to give the tenant a right of appeal to an independent tribunal The decision of that tribunal would be binding on both parties The object was to protect the tenant against the action of a harsh or unconscionable landlord in regard to the question of compensation for goodwill, the renewal of a lease, the value of improvements made by the tenant and the exercise of power under restrictive covenants If any member of the House could show that any hardship would be inflicted on the good landlord he would be quite prepared to consider amendments in order that such a landlord should not be damnified The sole object of the Bill was to remove a grievance which had been felt by tenants for a great many years He believed that the Bill, fairly administered, as it would be under the Tribunal which was being set up, and with the restrictions and limitations contained in the Bill, would go a long way to remove many of those grievances The Bill was not retrospective in regard to the question of improvements, because, for various reasons, such a proposal would be inequitable

Mr **Dalton** moved the following amendment —

"That this House, being desirous of removing the evils inherent in the present leasehold system, and whilst welcoming a measure dealing with certain of these evils in relation to business premises, regrets that the measure is so drawn as to preclude its application to other premises "

He said that at a time when support was slipping away from the Government in various directions an effort was being made in this Bill to retain, at any rate, the support of certain sections of the community, notably the trading, shopkeeping, and tenant interests in business premises He was afraid, however, that when those interests for whom the Bill was primarily designed had an opportunity of examining it rather more closely they would see that it was a very small, niggardly, and unsatisfactory satisfaction of what the Labour Party regarded as their just claims The present leasehold system was apt to give rise to very grave injustice The present law permitted landlords to confiscate the fruits of the past labour and enterprise of their tenants, and to hamper and penalise the future enterprise and labour of the same tenants The refusal of any compensation for improvements made before the passing of this Bill was a very grave defect There was a severe limitation to the business premises which would be included under Clause 12 A large number of tenants, who were professional men, had just as real grievances in kind, if not in degree, as the traders and occupants of business premises in the narrower sense There was a large number of medical men, dentists and other professional people who were just as liable to suffer from confiscation by their landlords if the goodwill which they had brought to their practices by the improvements they had made to their premises, as any other class of people Particularly in the poorer parts of London a great many doctors had built up considerable practices When their leases came to an end they were either turned out on the streets or were compelled to pay a grossly excessive rent by their landlords, who were quite aware of the goodwill which had been created in respect of those practices The same argument applied to Clause 14, and the principle that consent ought not to be unreasonably withheld in regard to the issue of new leases should be applied to professional people as well as to the occupants of ordinary business premises

Sir W **Joynson-Hicks** • Part II of the Bill is not confined to business premises but relates to all premises

Mr **Dalton** That is so far as not unreasonably withholding consent ?

Sir W **Joynson-Hicks** Yes

Mr **Dalton** said he was glad that that had been made clear, but it was still true that Part II in a restrictive sense only applied to leases granted after the commencement of this Bill

Mr **MacLaren** seconded the amendment He said that professional men had their goodwill just as much as any that ten deaths from diphtheria have occurred in the Higher Broughton district this year The ages of the patients were as follows 1, 17 months; 1, 4 years, 2, 5 years, 2, 6 years, 1, 8 years, 2, 10 years, 1, 12 years All these patients were treated at the Infectious Diseases Hospital of the Salford Corporation and all received antitoxin

Disinfection of Telephone Mouthpieces

Mr **Day** asked the Postmaster-General whether any further consideration had been given by his department with a view to disinfecting telephone mouthpieces against such epidemics as influenza —Sir **William Mitchell-Thomson** replied I consider that the arrangements for regularly disinfecting the mouthpieces of public telephones are adequate

MONDAY, APRIL 11TH

Infant Mortality in Palestine

Colonel **Wedgwood** asked the Secretary of State for the Colonies what were the latest figures for infant mortality in Palestine, distinguishing if possible between Arab and Jew, and what steps were being taken to improve these figures —Mr **Amery** replied The infant mortality-rate per 1000 births was in 1924, 184 83, 1925, 188 64, and 1926, 163 15 Similar figures in respect of the various sections of the population of Palestine are not available As regards the latter part of the question, 29 non-government infant welfare centres have been established in Palestine, to many of which the Government had given considerable financial assistance In addition, two Government centres have been established, where special training by experienced British nursing sisters is given to women who wish to take up infant welfare work A training centre for midwives has been established, at which 43 women have already qualified, and a scheme is on foot for establishing nursing clinics in a number of villages

Cholera in India

Mr **Short** asked the Under Secretary of State for India whether he was in a position to give the House any information with regard to the epidemic of cholera in the Bombay presidency, and what special measures were being taken to arrest the spread of the disease —**Earl Winterton** replied The epidemic appears to have started in the Dharwas district in February last and to have since spread to three other districts Figures relating to these outbreaks have not yet been received The measures taken to arrest the spread of the disease are a matter for which the Local Government are responsible, but my noble friend the Secretary of State has no reason to suppose that all possible steps to this end are not being taken.

Registration of Opium Consumers

Mr **Gardner** asked the Secretary of State for the Colonies whether the registration of opium consumers was now generally applied in the Straits Settlements and Federated Malay States, and, if not, how soon it would be applied —Mr **Amery** replied Opium consumers are not registered in the Straits Settlements or the Federated Malay States though the governments of those territories have put into operation certain measures which are designed to lead up to registration of consumers if and when circumstances permit

Mr **Gardner** asked whether any system of registration of opium consumers had yet been introduced in North Borneo, and, if not, whether representations would be made to the British North Borneo Company urging the desirability of taking this step, as a first measure towards the suppression of opium smoking contemplated in the Hague and Geneva Opium Conventions.—Mr **Amery** replied The government of the State of North Borneo has recently introduced an experimental and tentative system of registration of consumers of opium

Secretaries for School Medical Officers

Dr **Vernon Davies** asked the President of the Board of Education how many local education authorities provided their medical officers with secretaries, who accompanied these medical officers on their visits to schools for the examination of children, and what duties were performed by these secretaries.—Lord **Eustace Percy** replied As I have already informed my hon friend, the arrangement made by the Lancashire authority appears to be exceptional The duties of these clerks are, I understand (i) To prepare the cards for routine and special medical inspection, (ii) to prepare the summaries for the school medical officer's monthly and annual reports, (iii) to send notices to parents and arrange times of interview with the assistant school medical officer, (iv) to arrange appointments for dental treatment of cases referred by the assistant school medical officer, (v) to arrange appointments for ophthalmic treatment, (vi) to arrange appointments for the orthopædic surgeon, to take down his reports in shorthand and to transcribe them, (vii) to take down in shorthand the assistant school medical officer's reports on school sanitation and to transcribe them *These duties, except the first, are practically* one and all such as are undertaken by the clerical staff of any large local education authority and are usually completed at the offices of the local education authority In certain areas this is also true of the first where an inspection card is made out at the office when the child is placed on a School Register

Sale of Poisons by Licence

Lieut -Colonel **Fremantle** asked the Home Secretary what traders, if any, interested in the sale of poisons by licence, or otherwise, were represented on the committee now sitting to investigate the working of the Poisons and Pharmacy Acts, and when the report of the committee might be expected.—Capt **King** (Financial Secretary to the War Office) replied I have been asked by the Lord President of the Council, who appointed the committee to say that traders engaged in the sale of poisons, both by wholesale and retail, are represented on the committee I am unable to say when the report of the committee may be expected

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST GRADUATE COLLEGE, The Prince of Wales's General Hospital, Tottenham, N

Wednesday, April 20th —2 30 P M to 5 P M, Medical Skin and Eye Clinics Operations

Thursday —11 30 A M, Dental Clinic 2 30 P M to 5 P M, Medical, Surgical, and Ear, Nose and Throat Clinics Operations

Appointments.

Holmes, Evelyn M, M B, Ch B Manch, has been appointed Medical Officer in charge of After Care Clinics, and House Surgeon, Shropshire Orthopædic Hospital, Oswestry.

Lesslie, Nona S, M B, Ch B St And, D P H, Assistant Medical Officer, Dundee Education Authority

Morris, Eileen, M B, B S Lond, House Surgeon to the New Sussex Hospital for Women and Children, Brighton

Stratford, H M, F R C S Edin, Consulting Surgeon to the Westminster General Dispensary

Westminster Hospital **Smith**, B A, M R C S, L R C P, Lond, and **Holmes, D P**, M B, B S, M R C S, L R C P Lond, House Physicians, **Hatthornthwaite R A**, M B, B Ch, M R C S, L R C P, House Surgeon, **Slater, P P**, M R C S, L R C P Lond, Resident Obstetric Assistant

Certifying Surgeons under the Factory and Workshop Acts **Holman, A G**, M R C S Eng, L R C P Lond (Aylsham) Norfolk), **Wilson, H M**, M B, Ch B Glasg Linton, Cambridge)

Vacancies.

For further information refer to the advertisement columns

Ashington Hospital, Northumberland —Jun H S £100

Aylesford, Kent, British Legion Village Hospital &c —Jun P £100

Bethlem Hospital, Lambeth-road S E —Two H P's £25 per quarter

Birkenhead General Hospital —Senior and Second H S 's £200 and £150 respectively

Blackburn and East Lancashire Royal Infirmary —Third H S £150

Bradford Royal Infirmary —H S and H P Each £150

British Guiana —Surgeon Specialist £1200

Charing Cross Hospital —Obstet Reg

Charing Cross Hospital, Institute of Pathology, 62 65, Chandos-street Strand, W C —Asst Pathologist £500 for first six months

Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Great Barrow —Asst M O £250

Chester Royal Infirmary —Hon Surg to Ear, Nose, and Throat Dept

Coventry and Warwickshire Hospital —Hon S and Hon Asst P

East London Hospital for Children and Dispensary for Women, Shadwell, E —H P H S, and Cas O Each at rate of £125

East London, Municipality of the City of, South Africa —M O H £800 type All the crew have since been vaccinated and their quarters on board disinfected No native member of the crew is allowed to leave the vessel, but the European members are permitted to land on informing the medical officer of health or his representative where they are going No one except those engaged in unloading is allowed to go on board and the stevedores were offered vaccination before the work of unloading commenced I understand that the *Marharda* is leaving Dundee to-night

Mr JOHNSTON May I ask whether this cargo of jute has been disinfected in any way, if it is to be allowed to be sent to the mills, and if the workers are to be allowed to operate on the cargo of jute —Sir J GILMOUR The cargo of jute has never been handled or touched by any member of the crew and is being unloaded and placed in sheds

Mr JOHNSTON Are you going to allow it to be used in public works ?—Sir J GILMOUR I understand that the medical officer is satisfied there is no risk of cargo infection. It is not yet clear that those members of the crew who were diagnosed as having small-pox have actually got small-pox There has been no contact between the members of the crew and the cargo

Sir BASIL PETO Has the right hon gentleman any record of the number of cases among the 66 suffering from small-pox who have undergone recent vaccination ?—Sir J GILMOUR I think none of them, but I would not like to say off-hand

Mr JOHNSTON In the right hon gentleman's first answer did he not say that these cases had been diagnosed as small-pox cases, and did he not say in his supplementary answer that he was not sure that they were small-pox cases ? If they were small-pox cases, what guarantee has he that the raw jute has not been in contact with these people ?—Sir J GILMOUR Because the ship was loaded by other people at Calcutta, and the crew have never touched this cargo during the passage All I can say is that the wireless message which was sent to Dundee stated that they diagnosed these cases as small-pox On arrival every precaution was taken and the cases were removed to hospital, but it is very doubtful whether they are cases of small-pox, and, if they are, they are very mild cases

THURSDAY, APRIL 7TH.

Medical Certificates—Officers' Pensions

Major RUGGLES-BRISE asked the Minister of Pensions under what authority pensions or retired pay granted to officers under Article 539 of the Royal Warrant of 1914 for medical unfitness caused by military service had been reduced without, in each case, previous certification by the regulated medical authority that the disability did not seriously affect the officer's capacity for earning his living in civil life as required by the terms of the warrant —Major TRYON replied In every case where, for the purpose of the specially favourable terms of pension that may be granted under Article 539 to a Temporary Officer, it has to be decided whether his disability does or does not seriously affect his capacity for earning his living in civil life, the decision is supported by medical certification and, in addition, by clear evidence as to the officer's actual earnings

Silicosis in the Metal Grinding Industries

Mr W M ADAMSON asked the Home Secretary whether grinders' disease in the edge-tool trade was scheduled as an industrial disease, and what regulations were enforced for its prevention.—Sir WILLIAM JOYNSON-HICKS replied Silicosis has not been scheduled as an industrial disease under the Workmen's Compensation Act, but I have power to make special schemes under the Act to deal with it, and I am about to make a scheme which will embrace all the metal grinding industries including the edge-tool trade As regards prevention, a code of regulations is in force under the Factory Act

Mr W M ADAMSON asked the Home Secretary if he could furnish returns of cases in the edge-tool industry of grinders' disease, and whether he had any record of deaths due to this disease for the past ten years —Sir WILLIAM JOYNSON-HICKS replied Statistics of the incidence of this disease in the edge-tool industry are not available I regret therefore that a return of deaths caused by this disease in the industry cannot be furnished, but the honourable Member will find a detailed study of the subject in the report which was presented to Parliament in 1923

Schools for Defective Children

Mr GIBBINS asked the President of the Board of Education the number of defective children under the authority of the Board of Education, and what accommodation was provided for them —Lord EUSTACE PERCY replied According to the latest complete returns of local authorities, there were 32,975 mentally defective children in England and Wales in 1925 and 142,889 physically defective, of which 75,285 were classed as delicate and 40,400 as cripples There is accommodation in certified special schools for 17,233 mentally defective and 19,445 physically defective children The hon. Member will, of course, understand that the total number of physically defective children dealt with during any one year is considerably larger than the number for whom accommodation is provided in special schools, since most of the delicate children require only a relatively short period at an open-air school, and the majority of the cripples can be so far benefited by orthopædic treatment as to render them capable of profiting from the instruction in ordinary elementary schools

Secretaries to School Medical Officers

Dr VERNON DAVIES asked the President of the Board of Education if he was aware that 15 clerks were employed by the Lancashire education authority as secretaries to their school medical officers, with travelling and subsistence expenses while engaged upon their duties, and whether, seeing that in the case of other education authorities these duties were performed by the medical officers themselves, he would, in the interest of economy, arrange that the entire cost involved in this practice of the Lancashire authority should not be included in the Government grant —Lord EUSTACE PERCY replied The answer to the first part of the question is in the affirmative As regards the second part, my hon friend is mistaken in suggesting that in other similar areas these duties are performed by the medical officers themselves

Percentage of Insured Persons

Mr HERBERT WILLIAMS asked the Minister of Health what percentage of the population of England and Wales was insured under the National Health Insurance Act in 1913 and in 1926 or, if the figures for 1926 were not yet available, in 1925, and to what cause he attributed the change, if any.—Mr CHAMBERLAIN replied The percentage of the population of England and Wales insured under the National Health Insurance Act is estimated to have been approximately 32 per cent in 1913 and 36 per cent in 1925 The change in ratio is partly attributable to the change in the average age of the total population In the latter year also, the statistics of insured persons include disabled persons and persons over 70 years of age, while the 1913 statistics do not include such persons

Medical Members and Opticians Bill

Dr VERNON DAVIES asked the Minister of Health why no medical Member of this House had been asked to serve on the committee appointed to inquire into the registration of opticians, bearing in mind the fact that the subject was of great importance to the health of the people of this country, and that such a member could approach the question from a more detached standpoint than that of medical men actually in the practice of their profession —Mr CHAMBERLAIN replied I followed the usual practice in consulting the medical organisations specially concerned, and the three medical members were appointed on the nomination of the Royal College of Physicains, the Royal Society of Medicine, and the British Medical Association

Dr DAVIES Is my right hon friend aware that these gentlemen are probably representatives of those who are in actual practice at the present time, and is there any objection to having men on the Committee who have some knowledge of the subject, but who are not in actual practice, and may therefore be more or less unbiased ?—Mr CHAMBERLAIN I think it is very desirable that there should be representatives of those who have experience of actual practice, because I think that the opposition to the Bill comes very largely from that quarter

Lieut -Commander KENWORTHY Would it not be a compliment to the House if an actual member of the House were appointed —Mr CHAMBERLAIN That, of course, is a matter of opinion, but obviously members of the House will have their opportunity of discussing the Bill when it comes before the House

Consultative Health Council

Mr BENJAMIN SMITH asked the Minister of Health when the consultative council of his department on general health questions last met —Mr CHAMBERLAIN replied The Council last met on Dec 7th, 1921

FRIDAY, APRIL 8TH

Diphtheria Deaths in Manchester

Mr GROVES asked the Minister of Health how many deaths from diphtheria had occurred this year at Higher Broughton, Manchester, how old were the patients, whether they were treated at the fever hospital, and whether they received antitoxin —Mr CHAMBERLAIN replied I am informed

5 he found himself in Surat, and hearing of Asâlat an's request, volunteered his services through the East ia Company's President and Council Thenceforward was one of their servants, and as such used his influence various occasions in their behalf.

Boughton has long been regarded by historians as having tained the privileges of free trading from the Mogul nperor for curing his daughter the Princess Gahânârâ, o had been burned by her clothing catching fire But this cident is known to have occurred early in 1644, at which ne Boughton was at sea in the *Hopewell* Though Asâlat hân was in great favour with the Emperor, there is no idence that Boughton was ever at the Court of the Great ogul, and it is certain that, instead of an imperial fârmân ing granted to him, he obtained trading concessions by e order of Shâh Shujâ which were special to himself and ot general to the British. A fârmân was subsequently btained by the East India Company from the Prince at a st of 3000 rupees, granting free trade in his dominions, nd this was followed by others, each terminating on the eath or removal of successive rulers

NATIONAL LEAGUE FOR HEALTH, MATERNITY AND CHILD WELFARE

THE annual report of the League for 1926, representing its twenty-second year of life, shows evidence of increased activity all round Nearly 500 individual cases were dealt with, and while the majority came for help in finding temporary or permanent homes for children, convalescence, or accommodation for confinement, all sorts of applicants presented themselves from medical officers wanting help in starting child welfare centres to deserted husbands with young children left on their hands The Babies' Homes Department is responsible for three country convalescent homes for babies and toddlers, and, in conjunction with two other societies, for two nursery training schools and homes for babies in London. During the year 66 children stayed at the Marjorie Lumley toddlers' home, Maidenhead, 50 at the John Madocks home for definitely ill babies at Old Basing, and 67 at the Arkley home, near High Barnet The Babies' Hotel for healthy children of the professional class was moved from Snaresbrook to larger quarters at Clapham Park, and was always full Both here and at the Creagh Nursery Training School, in Kensington, students are received for training as nursery nurses. The Tired Mothers' Holiday Fund sent 16 women away for a fortnight's holiday, the mother in every case paying something towards the expense. A donation of £100 from the Ancient Order of Froth Blowers will enable this excellent branch of the League's work to carry on, just when the end of its resources appeared to be in sight. The publications department had a record year, the sales having reached more than 429,000 tems This is one of the few activities of the League which s not only self-supporting, but actually shows a profit

COCOA.

A BOOKLET of 48 pages with attractive photographs and coloured plates has been published by Messrs Cadbury Brothers Ltd, which tells the story of the cultivation of cocoa in a concise and instructive manner Starting with Cortez sailing home to Spain after his expedition to Mexico where he found the Emperor Montezuma, drinking *chocolatl*, (to use its original name) flavoured with vanilla and other spices, the author describes its introduction into Spain where it was mixed with sugar, into France under Louis XVI, and into England under the Commonwealth, and notes the establishment in London of the Cocoa Tree Club and White's Cocoa House, adjoining St James's Palace. Ecuador, Venezuela, Trinidad, San Domingo, Grenada and Ceylon have all contributed to the cultivation, the "Guayaquil" cocoa of Ecuador and the "Caracas" and "Criollo" of Venezuela cocoas being well-known names in early Victorian days Brazil too has taken up the cultivation, but the most remarkable progress has been made in recent years in the colony of the Gold Coast, which in 1891 exported raw cocoa to the value of only £4, whereas in 1925 the value was £8,000,000 In the last 15 years the production of cocoa has mounted from roughly 26,000 tons to ten times that amount. In 1910 the total world's production was 220,000 metric tons of 1000 kilos, and in 1925 the figure had risen to 495,000 tons, of which the United States of America consumed in metric tons 166,000, Germany 81 000, United Kingdom, 57,000, Holland 44,000 France 43,000, Spain 10,000, Italy 8000, and Canada, Australia and some other countries 52,000 The United States takes an easy first place by consuming one-third of the world supply. The Gold Coast has an area of about the same size as Great Britain and a population of 2,000,000 of whom only about 2500 are Europeans Its immense strides in material prosperity are remarkable In January and February of 1905 THE LANCET devoted some considerable attention to the subject of cocoa, and from these articles it can be gathered that the present day cocoa is very different from what it was in the early days According to Dr. A Wynter Blyth in a chapter on cocoa and chocolate in his well-known book on Foods published 45 years ago, the import of cocoa was only 9,000,000 pounds avoirdupois in 1875, and it could not be wondered at seeing the revelations of gross adulterations that had been made The perfecting of the processes of growth and preparation is evidently meeting its due reward

PRECAUTIONS IN THE USE OF X RAY EQUIPMENT

Messrs Watson and Sons (Electro-Medical), Ltd, Sunic House, 43, Parker-street, Kingsway, London, W.C 2, are issuing warning notices with every X ray equipment supplied, to ensure the safety of those who operate it A notice in permanent celluloid cover is fixed in the cabinet of the transformer, another is supplied loose for hanging on the wall of the X ray room, and a third, not celluloid covered, is attached to all instructions The text of the notice runs as follows:—

WARNING

1 Electricity is a fine Servant, but a very bad Master The following precautions should be carefully read and conscientiously observed by all who operate X ray equipment

2 The supply of current from the house main must be controlled by a double pole ironclad switch and fuses, with case suitably earthed and situated in an accessible position in the X ray room

3 *In no circumstances should any adjustment be attempted without first satisfying yourself that the main switch is off.*

4 Especial care should be taken in dealing with that portion of the equipment which carries the high tension current, the wires connected with X ray tubes, &c. Remember that ordinary protective measures such as rubber gloves, &c, are useless and that fatal results may ensue if these wires are touched when the set is in operation Keep at a safe distance from all high tension wires

5 All units partly or wholly constructed of metal, the Couch, Screening Stand, Tube Stand, &c, must be properly earthed. Terminals are provided for this purpose

6 Avoid slack high tension leads They should be replaced wherever possible by permanent rigid connections

7 Clean all insulators of ebonite, paxolin, porcelain, &c, each day with a dry cloth Accumulation of dust and moisture causes leakage and possible breakdown

8 Always operate the controls in the same order Standard practice should become a habit

9 Remember to see that all switches are in the off position immediately after making an exposure

10 Do not neglect to use the devices supplied to afford protection against scattered radiation The tube should be properly enclosed and every precaution should be taken to protect the operator from exposure to scattered as well as direct radiation.

First, last and always, never attempt any adjustment whatsoever without satisfying yourself that the main switch is off.

CHILDREN'S ALLOWANCES

A REPORT [1] presented to the Council of the Women's National Liberal Federation finds that the level of wages is influenced by the supposition that a male wage-earner may require to feed and clothe a wife and two or three children, and that, though in many cases these needs are imaginary, the belief in their existence underlies the different scale of payment offered to men and women for similar work When the introduction of machinery drove the workers into factories, men were accompanied by their wives and children, with the result that, however badly individuals were paid, the large family earned more than the small one The Factory and Education Acts, by forbidding young children to work and insisting on their attendance at school, reduced family incomes and made it much harder for the mother to go out to work, leading, in many cases, to economic dependence of the wife and children on the male worker So long as wages are based on the needs of the supposed average family of three children (actually found in 6 4 per cent of wage-earners), it is obvious that the large family is at a disadvantage, though the general living standard has improved owing to the growing tendency to restrict the birth-rate The report proposes that wages should be determined on the requirements of husband and wife, and that a uniform allowance, separate from wages and payable to the mother, should be made in respect of each dependent child This rearrangement of the national wages bill could be carried out either by contributory insurance or by the industrial pool system The latter scheme, which has proved successful on the continent—notably in France and Belgium—is favoured by the report, a section of which is devoted to a description of the working of children's allowances in other countries

CONGRESS OF PSYCHOTHERAPY IN NAUHEIM—The second General Congress of Psychotherapy will be held from April 27th–30th at Bad Nauheim, when lectures and addresses will be given by specialists from all parts of Germany The subject of psycho-analysis, for instance, will be dealt with by Schilder (Vienna), Goldstein (Frankfort-on-Main), Binswanger (Kreuzlingen), and Simmel (Berlin), while all branches of the subject from hypnosis to curative pædagogy will be included The Congress is intended not only for specialists but as an opportunity of interesting the medical profession as a whole in the mental side of therapeutics

PROGRESS OF CHARING CROSS HOSPITAL—At the annual meeting of the board of governors it was stated that of the £70,000 required for the purchase of the adjoining old building and site of the Royal Westminster Ophthalmic Hospital, £16,000 had actually been paid and a further sum of nearly £10,000 was available Mr George Verity, the chairman, announced that, through the generosity of certain well-wishers, the Institute of Pathology had been placed on a financial basis which had enabled the hospital to create a service that would be of the greatest value to the public In an address read to the York Women's Luncheon Club, Mr Philip Inman, the superintendent of Charing Cross Hospital, stated that it deals with 2000 accident cases every week

Notes, Comments, and Abstract

GABRIEL BOUGHTON.

BY GEORGE C PEACHEY,

SURGEON, BOUGHTON AND EAST INDIA TRADE.

THE early history of British trade in Bengal contains this picturesque story, according to which the concession that enabled the East India Company's servants t establish factories and to trade duty-free in that province were obtained through the magnanimous behaviour o a surgeon named Gabriel Boughton, otherwise Bowden who, having cured first an imperial princess and then on of the consorts of the Prince Shujâ, the viceroy of Bengal declined to receive any personal remuneration, but begged that in lieu thereof his fellow countrymen might be granted the commercial privileges they had long desired

The story, which is mentioned by Wadd in his "Mems Maxims and Memories" (1827) and many others, has been traced by Sir William Foster[1] to the copy of a memorandum formerly among the "Factory Records, Fort St. George" The original document is no longer extant, and there is internal evidence that much of it was derived from hearsay, and was in many respects inaccurate As will be seen, Boughton's alleged cure of the imperial princess, in 1636, is apocryphal, and his reported magnanimous refusal of compensation for services rendered in favour of trading concessions for his countrymen is equally unfounded. Still his influence in procuring permission to trade in Bengal, both for himself and the East India Company, whom he afterwards served, are facts which possess a lasting historical interest

Nothing of Gabriel Boughton's early history has been recovered until, in January, 1644, he sailed from Madras on the *Hopewell*, in which vessel he had probably left England as ship surgeon just two years before Meeting with very bad weather, his ship sprang a leak, and to save themselves from foundering they threw their lading overboard and made for Mauritius There the *Hopewell* fell in with the *Dolphin* which had met with similar misfortune, and after refitting, the two ships went out together to Madagasca and the Comoros; but finding themselves in no conditio to complete the voyage to Europe, they sailed for Surat which was reached in September, 1644 Asâlat Khân, a especial favourite of the Mogul Emperor, Shâh Jahân had long importuned the East India Company's Presiden and Council at Surat to supply him with an English docto probably for his own infirmities, and the difficulty of findin one who could be spared and was willing to accept th employment had alone prevented them from acceding t his requests But in January, 1645, Gabriel Boughton "late chirurgeon to the *Hopewell*, being at Surat, very wel qualified and willing to stay," was engaged upon "tha service and proceeded to Agra In August–September, 164 Boughton was at Balkh, in Afghan Turkestan—probabl he and the companion mentioned in his letters of thos dates were the first Englishmen to enter that town—an there is evidence that he was there in attendance as body surgeon on Asâlat Khân, who was taking part with th imperial forces in the conquest of Balkh, of which he ha been appointed governor by the Emperor Boughto describes it as "one of the unwholesomest countrie that ever I was in in my life, for never since my entranc into this city can I be in perfect health"

Asâlat Khân is said to have died in 1647, and Boughto is next found at Rajmahal at the Court of Shâh Shujâ who was then in charge of the province of Bengal Ther he was called in to attend one of that prince's favourit concubines, and having wrought a cure, he was taken int great favour and allowed ten rupees a day This prince ha been given by his father the government of all the revenue of Bengal, Bihar, and Orissa, and he offered to Boughton, if he desired to trade, freedom from customs and all other duties, and gave him two orders to that effect These privileges Boughton passed on to the President at Surat and about two years later a ship arrived from England and was permitted to trade free of all duties, probably owing to the good offices of Boughton with his patron He was still at Rajmahal in December, 1650, when he is described as "chirurgeon to the Prince," and there is reason to believe that he was alive in January, 1652, though he was certainly dead before August, 1653 His widow, "a Mogullana or Moorish woman," subsequently remarried, leaving issue by her first husband, a son, Gabriel Boughton, of whom nothing is known

The conclusions arrived at are that Boughton was at first a ship's surgeon trading with the East, that in January,

Lumleian Lectures

ON THE

MUSCULAR MECHANISM OF RESPIRATION AND ITS DISORDERS.

The Third Lumleian Lecture delivered before the Royal College of Physicians of London on March 29th

By Sir CHARLTON BRISCOE, Bart.,
M.D., F.R.C.P.Lond.,
PHYSICIAN TO KING'S COLLEGE HOSPITAL AND TO ST. JOHN AND ST. ELIZABETH HOSPITAL.

LECTURE III.*

In this lecture I shall try to apply the deductions of the former lectures to certain clinical conditions. In effect I believe I have shown three points: (1) That accentuated tonic conditions of muscle are liable to occur as the result of the conditions, reflexes, &c., described. (2) Such tonic conditions affect the muscles which operate on the thorax; no similar effect has been found in the diaphragm. (3) The persistent contractions of these muscles lead, as a rule, to an elevation of the whole or parts of the thorax. I have also shown that elevation of the thorax is unfavourable to the effective contraction of the diaphragm. There is thus a marked interrelation between the elevation of the thorax and defective diaphragm contraction, and the clinical conditions which I shall describe are equally related, and treatment will also show a good deal of common ground. I shall, however, separate as far as possible these two points, the result of tonic contraction on the one hand, from those of defective diaphragmatic contraction on the other, and I shall deal with the former and its connexion with pain forthwith.

Tonic Contraction and Pain.

It is common knowledge that an overtired muscle will ache, but the conditions under which it will cause definite pain are but little understood. My evidence that these muscles do cause the pains of which patients complain is: (1) That the muscles in question can be felt to be in a state of tonic contraction. (2) That they are tender to pressure. (3) That pressure on them elicits or causes an exacerbation of the pain of which the patients complain, and is frequently recognised by them as their particular pain. (4) That taking the strain off the muscle and enabling it to relax produces a cessation of the pain.

It is generally recognised that pain arising in nerves or certain viscera may be felt locally or have a distal reference. Baker[23] showed that skeletal muscle can give rise to referred pain in the case of flat-foot. I have verified this in cases of that condition and also have found referred areas and vasomotor changes in other muscles, the abductor indices and trapezius. The areas of referred pains for these muscles were described in my paper on the "Anginal Syndrome."[24] In that paper I also described the areas of reference of pain for the respiratory muscles. Thus, as with other muscles, pain produced by tonic contraction of a respiratory muscle may be local or referred or both.

More interesting than the question of the reference of the pain is the fact that frequently patients will recognise the pain produced by pressure on a sensitive muscle as being the pain of which they have had experience and of which they complain. Sometimes patients will even go further than recognising their own particular pain and will give their interpretation of it in such expressions as "that prevents my swallowing," "that grips my throat," or "it presses on my heart," or "it prevents my breathing." The remarks quoted in the last sentence have been forthcoming as the result of pressure on a sensitive triangularis sterni in different cases, and it is remarkable that a sensitive muscle should, in different individuals, be capable of producing sensations so variously interpreted.

Pain from any tonic muscle does not appear immediately the tonic condition is developed. The intensity of the muscle action also plays a part. The pain from the tonic muscle lasts only as long as the muscle is in that state and commences to decline when the tonic condition relaxes. An ache may persist for some hours. In one of my examples of a tonic trapezius muscle giving referred pain, the pain was longer in appearing if the arm alone was held out than it was if in addition a watering-can was held in the hand. Therefore, as a rule, there are periods following the diminution of the operative cause in which the pain is absent. This is well known in connexion with the common type of pain arising from gastric conditions. Similarly pains arising from over-exertion resulting in dyspnœa are intermittent. In functional cases it is more liable to be constant because the mental condition continues to operate.

Static Conditions.

In the consideration of clinical conditions interpreted in the light of these lectures the first example I shall give is purely static. Spinal curvature in the dorsal region leads to a widening of the intercostal spaces on the convex side. I have found a number of such individuals who, about the age of 50, complain of varying degrees of pain in the chest, more marked on exertion.

Thus in the case of a lady who complained of pain in the left chest on walking up a certain hill to her home, it was found that there was a spinal curvature with the convexity to the left in the dorsal region. The left third intercostal was tender to pressure, and the second, third and fourth intercostal spaces were more open than those on the right and the muscles were tonically contracted. Her pelvis was tilted which in turn was due to inequality in the length of the legs. Within a week of correcting this by the addition of half an inch to the heel she could negotiate the hill comfortably. When seen a month later the intercostal spaces on the right and left sides were similar; the muscles were inspiratory. Pain recurred when she neglected wearing the correction of the heel and again disappeared when the correction was employed. Anxiety over a son-in-law caused for a short time a temporary recurrence of pain, even when wearing the elevated heel.

The second instance I would bring forward is that of the prominent abdomen. If with this the shoulders are forward discomfort does not result. If, however, the shoulders are thrown back the ideal conditions ensue for accentuation of the thoracic type of breathing. The ache in the chest and pain in the neck, shoulders, and arms arising from the scalenes and intercostal muscles occur in these individuals, of whom the emphysematous and pregnant women are instances. It is an aphorism that the symptoms of emphysema are made worse by accretions of body-weight, a considerable part of which goes on to the abdomen. Reduction of the size of the abdomen tends to produce a more forward position of the shoulders in order to maintain the balance of the body. In due course Nature restores the balance of the pregnant woman. In many cases of this habit of body a sternal pain accentuated by pressure on the overtaxed triangularis sterni* has also been present. This muscle is one of the smaller muscles of expiration in the thoracic type.

Psychic Conditions.

The effect of persistent emotional reactions is well exemplified by the following case:—

A girl of 27, a cashier, complained of pain in the palms of the hands, ulnar side of the forearms and internal arm of persistent character day and night, and also of pains in the occipital region. The pains were accentuated by pressure on the scalenes and upper intercostals. At first she was

* The asterisks throughout refer to points demonstrated by means of lantern slides.

NEW PREPARATIONS

COMPOUND AGOTAN BRAND OINTMENT—We received this drug previously from Howards and Sons, Ltd , Ilford, in the form of tablets, in which shape we commented favourably upon it They now supply it as an ointment, the active ingredient being phenyl cinchoninic acid Agotan is of value by increasing the excretion of uric acid and urates in the urine, and has been found to give good results in various conditions of rheumatism and rheumatic arthritis, in lumbago, and in sciatic and other forms of neuralgia The manufacturers possess evidence also of beneficial results obtained in erythema and urticaria, and in chilblains The tablets (which were reported upon in THE LANCET of Jan 3rd, 1925) can be taken with advantage while the ointment is in local use Full directions for application are included with the drug

LAXA is a combination of sterilised wheat bran and agar-agar, and is so prepared that it is crisp and palatable when dry, while, if it should become tough with the absorption of moisture, those pleasant qualities can be restored by placing the food in the oven The directions are that from half a biscuit to two biscuits should be taken at each meal according to individual requirements, they can be substituted for bread or alternated with bread during the meal The use of agar-agar as facilitating bowel movements is well known, and the new combination is a palatable one It is supplied by Coates and Cooper, 41, Gt Tower-street, E C 3.

(1) **NEUTRALON**, (2) **BELLADONNA NEUTRALON**—Neutralon is a synthetic aluminium silicate with the addition, in the second case, of 0 6 per cent of extract of belladonna It is prepared by Schering Ltd , 3, Lloyd's-avenue, E C 3, and is a fine white odourless tasteless powder, insoluble in water but gradually splitting, under the influence of dilute hydrochloric acid, into aluminium chloride and silicic acid The pharmacological properties claimed for it are based upon this decomposition, it being assumed that the silicic acid will remain as a protective covering to the stomach while the aluminium chloride set free will act as an astringent A good deal of medical evidence has been published showing that the drug possesses antacid astringent and analgesic properties, so that its trial would be reasonable in affections of the gastric mucous membranes When there is an addition of belladonna the preparation should be administered with care if given for a long period.

THEORIES ABOUT HIGH BLOOD PRESSURE

WHILE the search for the cause of essential hypertension still proceeds, some find in the magic word toxæmia a solution of the whole problem To deal with toxins is one of the functions of the liver, hence, they say, let the liver be stimulated to action and the blood pressure will be lowered The failure of the liver to deal with the toxæmia is believed by Dr H R Harrower to be due to the absence of an internal secretion which he claims to have isolated and calls "anabolin" In a book which has recently been published ("Anabolin, Detoxication and Hypertension," Baillière, Tindall and Cox, 1927, 10s 6d) he gives reasons for his conviction that "anabolin" is neither histamine nor choline, and that it does not contain enough of these substances to produce the effect of lowering blood pressure that he claims for it The clinical records designed to prove that anabolin given by the mouth to patients with essential hypertension has this effect are disappointing since the cases are not described in sufficient detail Moreover, the criticism based upon the fact that blood pressure has a habit of falling in these patients, at any rate temporarily, is met by the statement that the fall cannot be coincidence in every case The facts that in an historical introduction Dr Harrower is grouped with Glisson, Malpighi, and Claude Bernard, and that elsewhere in the book he refers to his great achievement (parallel with the discovery of insulin), are unlikely to influence men of science in favour of his claims

"HE TOLD HIM ABOUT——, A SIMPLE HARMLESS PREVENTATIVE"

To the Editor of THE LANCET

SIR,—I have just seen a half-page illustrated advertisement in an American medical journal which represents a youth, with an expression of eager anticipation, listening to his father's words The latter impressed, as we are told, by knowledge of "the dangers of hidden diseases and their serious consequences in later life" is, by reason of his son having reached "the age of maturity, the dangerous age," advising him concerning the course of action which he should adopt in relation to his sexual life His task over, the father feels that "he had done his duty" and "solved a difficult problem in an efficient and simple way" We can imagine the nature of the counsel which, as a wise father, he has laid before his son With a vivid recollection of his own temptations he has dwelt upon an ideal, which he once held though he may possibly have failed to realise That ideal may have had a religious or ethical foundation but it would, in any event, be associated in the boy's mind with a chivalrous conception of the dignity and purity of womanhood

But no, our imagination runs astray, for here we have a father who devoid of any form of idealism is doing his utmost to make his son even as himself What did he say by way of counsel? "He told him about——, a simple, harmless PREVENTATIVE against diseases, a product well-known to the medical profession." In other words he essayed to show him how he might indulge his lust without paying any physical penalty His efficient and simple solution of his son's difficulty was to rule out the higher and to be ruled by the lower factors in his nature

To whom can such a libidinous advertisement commend itself? Only when all methods of dissuasion from sexual promiscuity have proved futile, when all worthy ideals have failed in their appeal, should the individual be instructed how to give rein to his erotic instincts by the adoption of measures calculated but never guaranteed to secure immunity from disease But surely this counsel should be a last resort, given not primarily for the sake of the individual, but for the safety of other members of society whom he might injure

I trust the journal will disclaim an advertisement likely to pervert rather than sublimate the physical strength of Young America I am, Sir, yours faithfully,

CUSTOS

A SILENT HANDICAP [1]

THIS book is a sympathetic account of the lives of several children born deaf, and every chapter helps to build it into a first-class argument for the higher education of the deaf subject The handicap under which these children and their similars are placed is well explained, sympathy with them is demanded throughout in a logical and not a mawkish way, and the varying attitudes of those who find themselves in contact with the deaf are brought out with precision and considerable humour The passages which describe the evolution of Geoff, the portrait of Mr Dockety, and the pictures of the various social and educational functions at which the children are present, all show insight and a really tender understanding The different futures which lie before the born deaf are shown to depend upon the provision of proper opportunities for development, as well as on the special aptitude of the subjects As propaganda for the promotion of a training for the deaf enabling them to use for the public good the gifts which they normally possess the book will be useful, and as a well-told and interesting story it should be a success

VENOMOUS SPIDERS

To the Editor of THE LANCET

SIR,—In your issue of Dec 11th, 1926, you commented on the venomous bites of certain spiders This sort, a black spider with a red spot on its back, has an extensive distribution It is not uncommon in Australia, and when it bites a person, as occasionally happens, the consequences are serious, as it causes intense generalised pain, which may last for several days I enclose a cutting from an Adelaide daily newspaper which shows, if the facts are to be depended on, that the trap door spider also is capable of inflicting serious harm and may be fatal I have some specimens of this spider's lair, with the trap door complete It appears to be identical with the form met with in Europe I have not, however, seen the spider that inhabits it

While on the subject of unusual poisons I should like to ask what truth there is in the statement (Timbs' "Doctors and Patients") that the secret poison used by the gypsies to kill pigs, &c , is a powder consisting of the spores of a fungus, which, when it enters the mouth, grows into innumerable long, fine filaments that enter the air passages and lungs and cause speedy death It is also stated that a boy in Italy died in this way in 1800

I am, Sir, yours faithfully,

F LUCAS BENHAM, M D , M R C P

Semaphore, South Australia, Feb 28th, 1927 egree of thoracic breathing which promotes an ssociated ineffective diaphragm contraction.* The rganism seems to attempt to remedy the defect ather by rapidity than by depth of respiration Hence in excessive thoracic breathing the defect is perpetuated and panting ensues In these dyspnœa is present on exertion In talking a breath is taken too frequently, and, of course speaking when out walking is practically impossible. The pulse is rapid and may be irregular in size Pains arising from the respiratory muscles are frequent at night when posture may accentuate the condition Giddiness and a tendency to faint also occurs Perhaps a few words may be said on the relationship of the circulation and respiration

---

[1] A Silent Handicap By Ann Denman London Edward Arnold and Co 1927 Pp 313 7s 6d

[2] The cutting describes an inquest on an infant whose death is said to have been due to the bite of a trap door spider of a species "which was both venomous and rare" The case was stated to be the first on record in which a person had died from the bite of a trap door spider

Respiration is, of course, developed as an accessory to the more important circulation The supply of blood must be either by gravity, aspiration or pumping action The first two are more or less constant in any given position The pump may vary Considerable importance has been attributed[25] to the presence of positive intra-abdominal pressure whereby the blood is driven from the abdominal cistern up and to the heart Such positive pressure is dependent on the walls of the abdomen, either muscular or connective tissue In those tending to the thoracic type the diaphragm descends but little during inspiration and the muscular parts of the abdominal wall are inactive During expiration the muscles of the abdominal wall may be contracting but the diaphragm is inactive. Pressure can therefore, never be high In contrast the diaphragmatic type in inspiration, contract the diaphragm and muscles of the abdomen simultaneously, but relax in expiration In inspiration, therefore the intra-abdominal pressure must be relatively high but in expiration very low If the diaphragmatic type changes to thoracic the intra-abdominal pressure and blood-supply will not be that to which he is accustomed It is a surmise as to what may happen in any given case From the clinical point of view cardiac rapidity frequently results In the nervous as in life examination, the pulse can often be reduced from 100 to 70 by making the individual breathe with the diaphragm In the case of a candidate for commission, suitable in every respect except for cardiac rapidity, the pulse under examination when supine was 130 per minute By the means to be described later of making the diaphragm contract the rate came to 80 at once It is not my purpose to pursue this question further, but to offer a simple explanation for the symptoms in these cases and to accentuate the point that when diaphragmatic action departs from the normal for the individual alteration in pulse may follow

Thus excessive thoracic breathing promotes dyspnœa under many different circumstances I suggested this mechanism as being a possible factor in cardiac dyspnœa I believe it is the main factor in pregnancy emotional conditions, and the convalescent stage of pleurisy.

Before passing to consider treatment, we may summarise our conclusions An inspiration must continue until a certain amount of air has passed into the lungs, and when this has been attained the inspiratory act will cease. There is a selective action residing in the muscles dependent on the stretch under which they may be, and this decides whether that muscle or its neighbour will contract If the inspiration is prolonged the muscles which were under a diminished degree of stretch at the commencement of the act will eventually be called into action The diaphragm is the principal muscle of respiration and respiration should be carried out by means of contraction of the dome of this muscle Conditions extraneous to the respiratory system proper arise, in which the normal relationships of stretch in the respiratory muscles are altered This leads to a substitution of the mechanism of the thorax at the expense of the diaphragm and induces dyspnœa This substitution compels certain muscles of the thorax to action not inherently natural to them and of the nature of persistent tonic spasm Excessive tonic contraction, if it persists gives rise to tenderness on palpation and to subjective pains which may be local or referred

CONCERNING TREATMENT IN GENERAL

It is obvious that if I am correct in my views that persistent tonic contraction of muscles is the cause of pain and excessive thoracic breathing of disability as mentioned above these symptoms should be relieved by any means through which strain is removed and the muscles are enabled to relax The tonic muscles are those connected to the thorax, and so concerned with thoracic respiration Relief can be afforded in two ways (1) by promoting increased contraction of the diaphragm, (2) by mechanical means instituted for the direct relief of strain

There should of course, be no impediment to the descent of the diaphragm Clothes on the abdomen should be loose This applies as much to men's clothing as to that of women The tape of pyjamas should be fastened quite loosely at night and the leather belt, so frequently adopted and looked upon as a charm by the labourer should be given up The latter is usually a continuation of the mode adopted in youth, when the respiratory mechanism is very labile and capable of free accommodation Such a belt is useful in youth to promote a development of the upper part of the thorax which is thus forced into action at the expense of the diaphragm It should not be allowed after the age of 40

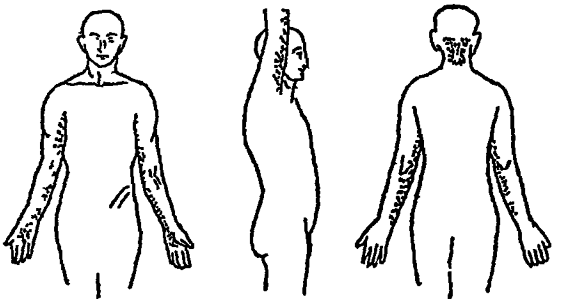
RE-EDUCATING THE DIAPHRAGM.

Under this heading also comes the question of training people to contract the diaphragm There are a certain number of people such as asthmatics, and individuals who have had some inflammatory condition in the chest in whom the diaphragm appears to be inactive or to be what may be described as lazy. There is no doubt that training the diaphragm to contract voluntarily is most important and leads to good results I would however say a word of caution on the means by which this should be produced It is well known that if an individual is directed to take a deep breath, in the majority of cases this instruction is obeyed by a big thoracic elevation and without any protrusion of the epigastrium. From the result of considerable experience I am quite sure that at first no mention of breathing should be made. The individual should be directed to push out the abdomen In some cases this command cannot be obeyed until after considerable encouragement It is the more easily carried out with the patient in a semi-recumbent position with the back not extended—i e not on a flat back bench, but on one which is rendered hollow so that the spine will not be extended This exercise should not be persisted in for too long a time Volitional efforts at respiration produce fatigue Instructions should therefore be given that four or five efforts at a time should be made for a few days and afterwards be increased It is advisable to fix definite periods, such as when the clock strikes the hour before meals, &c I mention this with some detail because when an individual has acquired a faulty habit of voluntary breathing, especially after instruction it is frequently difficult to get him to revert to the proper type * I have found this treatment beneficial in cases of asthma and it should be continued till the individual has a complete volitional control of his respiratory mechanism so that he can on command contract the diaphragm to the full I have not met the asthmatic patient who can stop his attack by voluntary breathing in this manner, but I have seen several who can abort an attack if they wake up before it has fully developed, and this remains a permanent feature of their disease and cannot be considered as one of the transient benefits of psychic influence.

Still under the first heading of promoting a contraction of the diaphragm I must refer to the much debated question of the value of psycho-analysis.

thought to be an instance of occupation neurosis (Fig 1) Her work involved standing all day and writing with the elbows unsupported She was of the build and type of visceroptosis A tracing of her chest showed marked thoracic type of breathing, and this abnormal breathing indicated the diagnosis, the pains being referred from the over-tonic muscles

FIG. 1



Referred pain from ant scalene muscle Functional case

I shall refer to this case later under treatment As stated in my second lecture, the respiratory habit of functional disease is thoracic, whether in men or women Many cases showing this habit occurred during the war, and were discharged as neurasthenics

Thus a man, aged 26, who was discharged in May, 1919, as neurasthenia, dated his illness from bronchitis in 1915 and sunstroke in 1916 and 1917 His complaint was that three or four times in a week he woke with a start, sat up and struggled for breath There were no physical signs in the heart or lungs and there was entire absence of any epigastric protrusion on breathing Pressure on the triangularis sterni produced pain and sensation of strangling Instructions were given to remedy the defective action of the diaphragm A fortnight later he reported "better sleep and on only two nights was there any wheezing" He was instructed to continue, and in a further month reported "no attacks and good sleep," and the pain was not produced by pressure on the muscle formerly tender

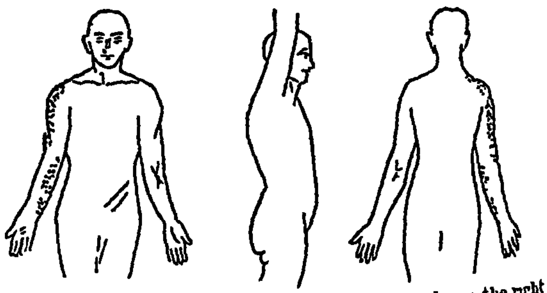
Another man discharged with D A H complained of rapid heart on exertion or excitement, with pain in the upper part of the chest The heart sounds were normal, the pulse 150 He again had lost diaphragmatic breathing, and the second intercostal space was markedly sensitive to pressure He was given similar instructions, and five weeks later Dr Wiltshire's note reads, "much better, pulse steady, 80 per minute" The heart had ceased to bother him 14 days after being first seen, and had only been troublesome on one occasion after having had two drinks with his father A further note nine months after his first visit stated that he was keeping well and his breathing was normal There were no pains in the chest

Gastric Pain —There is no need for me to do more than to remind you of the very large number of cases who complain of pain under the heart after food As I have indicated in my second lecture, these originate from a persistent tonic condition of the fourth or fifth intercostal muscle It is not clear why that part of the muscle which is in the nipple line should be most tender. This is the point at which the external intercostal muscle ends, for in the intercartilaginous space the place of this muscle is taken by fascia This point is also the apex of the inverted arch formed by the rib and costal cartilage, an arch which is more narrow and is therefore deeper than that of the other ribs

Pain of Pleurisy —Nor is it necessary to give details of the acute pain of pleurisy As I have stated, the muscles in the neighbourhood of a patch of pleurisy become tonically contracted Pain is accentuated by pressure on the tonic muscle Three points are, I think, worth mentioning First, when pleurisy is located near the lower part of the sternum the triangularis sterni is particularly concerned in fixation, is tonically contracted, and gives rise to pain appreciated behind the sternum I have seen three cases in which pain came on suddenly, as commonly occurs in pleurisy, in two cases pain was so acute as to cause the doctors to make a diagnosis of angina pectoris * The third was not so intense, and was thought to be due to pericarditis The second point is the frequency with which the onset of pleurisy at the base is accompanied by pain in the shoulder or arm* (Fig 2) The third point is that apical pleurisy is also frequently associated with pains of similar distribution * From the short description of muscle actions in pleurisy given in my second lecture, the origin of these pains in tonically contracted scalenes and upper intercostal muscles is readily appreciated I here show the distribution of the pain in the arm arising as in a case of basal pleurisy, and in a case of apical pleurisy Dr Greenop while resident at the City of London Hospital investigated the question of referred pain in pleurisy (chiefly of tuberculous origin) in 50 cases During the course of the attack pain was referred to the area over the shoulder in 32 cases—64 per cent This is one of the areas I have described referred from the scalenes and upper intercostal muscles In these 32 (1) pain was referred down the arm, as far as the wrist in two instances, (2) the pain was definitely accentuated by pressure on the scalenes in seven instances The pain of pleurisy seems to be more intense in an individual of thoracic type

Chest Pain on Exertion —Pains occurring on exertion are commonly intensified and often recognised by pressure either on the triangularis sterni or on the scalenes, and, or on the upper intercostals, and more frequently on the left side Thus a male infirmary patient, aged 56, who could not walk the length of the ward without getting pain in the sternal region, and being obliged to stand still, recognised his pain when the tonic triangularis sterni on the left side was pressed upon * Similarly, a chemist aged 56, whose limit had been generally a hundred yards, but on occasions a quarter of a mile, recognised the pain which caused him to stand still When the third left intercostal space was examined with the finger shortly after an attack, the pain was produced and followed the usual course across the chest and down the left arm

FIG 2.



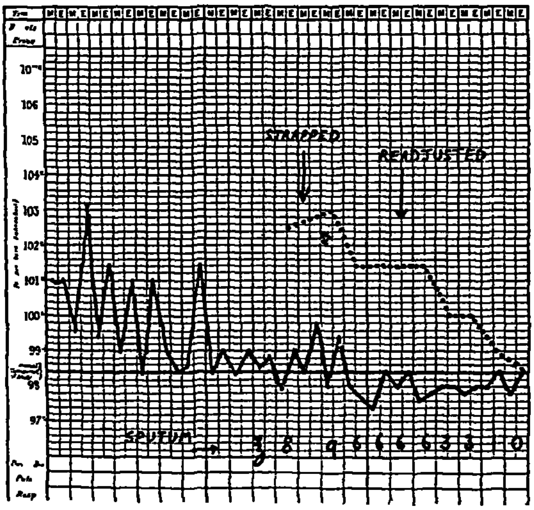
Area of referred pain from the ant scalene muscle on the right side From a case of pneumonia affecting the right lower lobe 36 hours after onset

With advancing age and diminished elasticity of the lung there is a greater liability to symptoms of stress owing to the accentuation of strain on the thoracic muscles As I stated in Lecture II, they are battling with an unyielding thorax, the result of calcification of rib cartilages In general, the more a man inclines to the thoracic type through life the more will he be affected by this stress in advancing years, and if he has a positive Wassermann reaction the earlier in life will such symptoms occur, by reason of the early calcification An apparent exception to this is seen in old people who give up thoracic breathing and rely on the diaphragm This occurs as the thorax becomes completely fixed, is a sign of giving up the contest, and is accompanied by an amelioration of the previous pain on exertion Much exertion is, however, impossible and he refrains, not on account of pain, but because "I cannot get my breath"

Dyspnœa —Turning now to dyspnœa, an important cause of shortness of breath, is an excessive

When applied in a case of pleurisy the spring is placed on the sound side On the affected side the belt should pass over the area where the intercostal muscle is most sensitive Its effect, when suitably adjusted, is to cause cessation of the spasm in the muscles controlling the ribs in the affected area. This is immediate, and should be the criterion as to adjustment. The persistent pain (but not that on coughing) begins to diminish forthwith, and has usually disappeared within ten minutes to half an hour I believe that this is an additional proof of my thesis that the pain is produced by a tonic contraction of the muscle Not only the intercostal, but the other muscles, such as the triangularis sterni and transversalis, cease to be tender, and the referred pain disappears At the same time the frictions are heard more distinctly This is explained by the fact that epigastric protrusion is induced or increased showing greater movement by the diaphragm The fact that this epigastric protrusion is induced when previously it was absent is strong evidence that pleurisy per se does not cause complete inhibition of the diaphragm I gave a full explanation in my second lecture It is a further advantage that, if desired, either a poultice or ice can be applied over the webbing of the belt

FIG 5.



Showing diminution in quantity of sputum as the result of lower thoracic constriction

Short of relieving the action of the muscle by the means indicated above, I feel sure that heat is the best local application whether by poultices, hot-water bottles, diathermy, or heating of dinner plates and holding them to the affected area, as was the habit of a patient with retrosternal pain prior to trying strapping.

The triangularis sterni has been mentioned before as being particularly liable to become tender, and pressure upon it produces pain in the lower sternal region, which is frequently recognised by the patient Assisting the action of the muscle is a rational method of treatment The part of the muscle which can be palpated is attached to the xiphisternum mesially, and to the back of the sixth rib laterally I propose to mention four types of case in which such a mechanism as a spring belt gives great relief

The first is the patient who wakes at night with retrosternal pain in the referred area of this muscle Whether this muscle is overtaxed as the result of a dream, or getting too low in the bed so that the spine is extended, I do not know However, the application of this belt at the level of the lower end of the sternum and xiphisternum relieves the pain at once, and these individuals do not forget to place the belt under the pillow on going to bed The second type is found in cases of severe colds with mild bronchitis of the larger tubes where low sternal pain develops Assisting the muscle relieves this pain The third type is caused by injury.

As an instance of this, I quote the case of a motor-lorry driver who, while starting his engine, suddenly felt something snap in his chest Pain developed instantly, of such severity that he could not move and believed that he was dying He was taken home and diagnosed as angina pectoris The diagnosis was, however, clear when bruise discoloration appeared in the fourth intercostal space Constriction at this level relieved him at once This accident is becoming more frequent.

The fourth type is well represented by the case of a doctor, aged 60, who developed pain if he walked 100 yards, and was advised to give up work on account of coronary artery sclerosis diagnosed from this retrosternal pain on exertion He has been wearing one of these belts for seven years, and now only occasionally gets pain, and carries on a big practice, largely on foot.

This method of restriction of the lower part of the chest will frequently also relieve pains arising from the upper part of the chest, and I believe it does so by inhibiting thoracic and promoting diaphragmatic expansion, and so diminishing the necessity for excessive thoracic respiration. For instance, in a case of tenderness arising from a tonic condition of the scalene,* promotion of abdominal respiration will relieve that tonic condition, at the same time it will cause the muscle to contract actively and so elevate the chest during inspiration * At first sight it appears to be a paradox that increasing the contraction of the muscle should relieve pain, but again I believe this supports the theory I have put forward that it is the tonic contraction without relaxation of muscle and not the intermittent active contraction which is the cause of the pain

There is a certain type of case which *develops pain* on exertion in the chest, neck or arm, in whom the heart is apparently sound The pains last for 18 months or two years, and then cease They may accompany the commencement of rise of blood pressure These are individuals who were mainly thoracic in type, and in the course of time are turning to diaphragmatic breathing They are usually between 50 and 60 years of age, a period during which many degenerative changes are taking place, one of importance being the onset of calcification of costal cartilages These are relieved by thoracic constriction* which has to be continued for 18 months to two years, and then with the disappearance of pain can be discarded

Posture

I have mentioned posture on hands and knees as a means to be adopted in children of promoting diaphragmatic contraction The converse occurs on extension of the spine which promotes thoracic movement In children of poor thoracic development who elevate the thorax in inspiration but do not contract the intercostal muscles, considerable improvement follows the adoption of a posture in which the thoracic spine is fully or over-extended for an hour twice a day It is most efficacious in those between 6 and 10 years of age

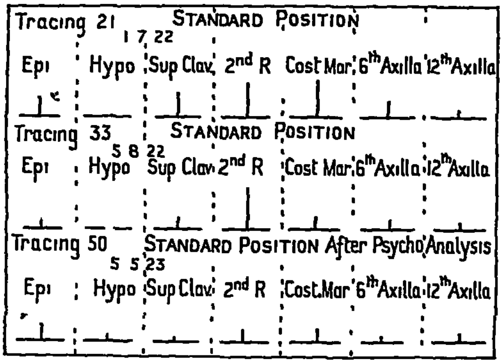
After pleurisy when the intercostal muscles on one side remain contracted, and there is a tendency to the production of a lateral spinal curvature, some considerable amelioration can be produced by making the individual lie on the sound side, the spine extended, and with a pillow or sandbag under the lower side This causes the upper (the affected side) to become convex, to open the intercostal spaces, and promotes contraction It may be painful for the first few efforts, but should be persisted in

CONCLUSION.

In conclusion, the negative result of a search of the literature has made me conclude that the mechanical side of respiration has not received the

I show you a slide of a patient to whom I referred formerly. She was first seen for pains in the arms and neck The first and second show you her type of breathing when first seen, which is nearly purely thoracic, and the third shows you the type of breathing after psycho-analysis by Dr Strauss Her neurosis was due to repressed fear The experience which frightened her was the falling of a bomb near her during an air raid The emotional component of the experience had undergone the process of repression The change in her general condition which followed this treatment, and the relief of pain arising from the upper respiratory muscles, was most remarkable (Fig 3)

FIG 3.



Effect of psycho analysis First and second tracings before, third after psycho-analysis In the latter the thoracic movement is markedly decreased

No case in which pleurisy or pericarditis have developed should be allowed to get up before he can produce a satisfactory protrusion of the abdomen, by whatever means procured * In children a return to the method of progression of their original progenitors—on hands and knees, is useful, but such means are not favoured by adults.

Not infrequently in clinical work we have to deal with a marked condition of this kind which may be termed " lazy diaphragm " It is apt to follow severe conditions of pleurisy, pericarditis, and abdominal operations I would remind you of the Japanese treatment for this condition of lazy diaphragm, which consists in inserting an exploratory needle into one of the lower intercostal spaces I have tried this method in two cases only, and with success In them shortness of breath persisted after operation It is quite possible that the axillary portion of the diaphragm can become overstretched and not be in a condition to react to a nervous impulse, and that a local stimulus of the nature of an exploratory needle promotes a contraction which is followed by a shortening of the fibres, and a suitable degree of stretch is reinstated

1 *To Promote Contraction of the Diaphragm* —In all except the most marked cases, thoracic breathing can be converted to diaphragmatic by simply depressing forcibly the lower ribs towards the pelvis (Fig 4) This procedure prevents the full thoracic mechanism coming into play, and so the diaphragm must perforce contract The muscle-fibres arising from these ribs are put under stretch For a permanent effect some mechanical means of holding these ribs depressed and preventing the recrudescence of the thoracic activity must be employed. Such method may be adopted alone or to assist voluntary efforts temporarily or permanently. I prefer the method of education rather than such mechanical assistance, but find mechanical assistance mentioned below essential in certain instances

Another example of the value of forcing the diaphragm to work by restricting the expansion of the chest is seen in persistent basal bronchitis I believe that a number of these cases persist because contraction of the dome of the diaphragm is insufficient to promote expansion of the lower lobes and thus to get sufficient air behind the mucus to dispel it

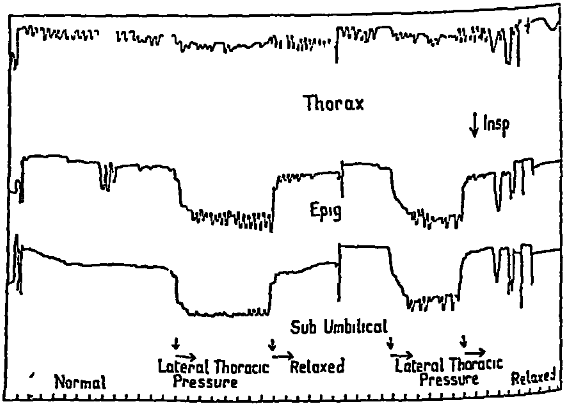
Fig 5 shows the diminution in the quantity of sputum as the result of lower thoracic constriction. This patient had had bronchitis for several weeks, he was admitted under my care, and as he had run the gamut of the usual expectorants was given an iron tonic This produced no amelioration The quantity of his sputum was measured, and a piece of strapping applied so as to constrict the lower thorax It was changed once to promote further constriction, and the slide shows a fall of temperature and the diminution of sputum which rapidly accompanied this treatment This mode of treatment is also useful in some cases of more chronic bronchitis.

As an example of this, I may quote the case of a retired army officer, aged 62, who, following influenza three years previously, had been expectorating about a coffee cup full of sputum daily in spite of going abroad during two winters. The sputum showed a pure infection of *B influenzæ* His type of breathing was rather markedly thoracic In ten days after lower thoracic restriction he had ceased to expectorate and his dyspnœa on exertion was much improved In the last 18 months he has not relapsed and wears the apparatus night and day

This is a useful method, both in adults and in children, for the latter a skein of wool may be employed

2 *To Relieve Stress on Muscle* —Under the second heading the effect of relief to the overtaxed muscle is striking in cases of pleurisy, but is valuable in other types of tonic muscles The old method of applying strapping seems largely to have fallen into abeyance, the reason for which is, I think, that any complete constriction of the chest is intolerable When applying strapping to a chest, and to be effective it has to be applied round the whole chest, the first thing that patients do is to try to take a deep breath, and when this is found to be impossible they become alarmed, and say they are being choked or strangled, and insist on being set free To obviate this I now use in all adult cases where restriction is employed a piece of webbing in the form of a belt, in the course of which is inserted a spring The objection is removed, for the patient can take a deep breath, and therefore does not experience those uncomfortable and terrifying sensations The permanent effect is, however, the same, and when the effort ceases the chest is restored to the required dimensions This belt also is of advantage because it can be readily varied, whereas strapping adjusted remains in position, and, further, tends to stretch a small amount, and therefore the constriction does not remain constant or as originally desired.

FIG 4



Effect of compressing lower thorax (*a*) on the upper thorax diminished movement, and (*b*) on the diaphragm, elevation of level of the abdomen and increased movement Functional case normal and characteristic of myxœdema. In Case 12, where the basal metabolic rate was only −3 per cent, it is to be noted that the patient was actually receiving thyroid extract when the estimation was carried out. A study of the table shows that no less than 18 of these cases suffered from menorrhagia as a symptom after the onset of myxœdema. In only four was menstruation regular and normal and in one instance a tendency to amenorrhœa was found. In this series therefore, 78 per cent of the patients in whom myxœdema developed before the natural menopause suffered from menorrhagia.

TABLE I.—*Myxœdema Developing before Natural Menopause*

Cases occurring after Natural Menopause

Table II shows a series of 15 cases of myxœdema developing after the natural menopause. The average age of the menopause in this group was 49½, and menstruation in all cases had previously been normal. The average period of time between the cessation of menstruation and the date at which these patients reported for treatment for myxœdema was 8½ years an interval which seems sufficient to justify the assertion that, in this series at any rate, the onset of myxœdema was not the cause of amenorrhœa; rather does it confirm the opinion which has frequently been expressed that myxœdema is a disease which tends to develop after the menopause and normal ovarian activity has ceased.

TABLE II.—*Myxœdema Developing after Natural Menopause*

Case	Age	Basal metabolic rate (per cent)	Menstruation before menopause	Menopause	
				Years previously—	At—
1	51	—	Regular and normal	4	47
2	56	−53·7		3	53
3	59	—		7	52
4	75	−21·8		25	50
5	56	−22·9		6	50
6	49	−26·7		2	47
7	51	−26·3		4	47
8	50	—		3	47
9	67	—		15	52
10	50	−15		3	47
11	60	−14·3		8	52
12	56	−11		6	50
13	70	−42		20	50
14	55	—		9	46
15	60	−35		10	50

Taking into consideration therefore, the 38 cases already quoted in Tables I and II, it appears that myxœdema develops before the natural menopause in rather less than two-thirds, and in the majority of these patients (78 per cent) it is accompanied by menorrhagia. In the remainder rather more than one-third, myxœdema develops after the natural menopause, and in this group menstruation previous to the menopause was quite normal.

Cases Occurring after Premature Menopause

Table III shows a series of three cases which cannot be grouped either in Table I or Table II, owing to the fact that the menopause occurred prematurely. The cases were all quite typical of myxœdema, and the basal metabolic rate was subnormal in all three, −35 per cent, −20·3 per cent, and −28 per cent. respectively. The onset of the disease however did not occur for many years after the menopause. In Case 1 the interval between the cessation of menstruation and the onset of symptoms of myxœdema was eight years in Case 2, 12½ years and in Case 3, 18½ years, so that here again it is extremely unlikely that the cessation of menstruation was in any way due to the thyroid disturbance which developed subsequently. In Case 3 the symptoms of myxœdema were first noticed 18 months after the removal of a retrosternal goitre. The goitre had been present for four years before operation was undertaken so that the interval between the menopause and the onset of thyroid symptoms in this case was 14½ years. The cause of the premature menopause in Case 3 was not discoverable, but in Case 1 it occurred after a stroke, and in Case 2 after pregnancy, menstruation appearing on one occasion only after the child had been born.

TABLE III.—*Myxœdema Developing after Premature Menopause*

Case	Age	Basal metabolic rate (per cent)	Menstruation before menopause	Menopause		Myxœdema for—
				Years previously—	At—	
1	45	−35	Regular	11*	34	3 years
2	52	−20·3	,,	14†	38	15 months
3	60	−28	,,	20	40	18 months‡

* Following stroke
† Following pregnancy (one period after and then stopped)
‡ Following thyroidectomy performed for retrosternal goitre which she had had for four years

Cases Occurring after Artificial Menopause

Table IV. shows a series of 15 cases in whom the artificial menopause had been induced either by surgical measures or X rays for menorrhagia. All these patients have since developed typical symptoms of myxœdema and are now under treatment with thyroid extract. The question that arises is whether the menorrhagia in these patients was an early symptom of myxœdema. Unfortunately, it is impossible to speak with any certainty as to the state of the pelvic organs at operation in all these patients as gynæcological treatment in the majority was undertaken some years ago and not at this hospital. Consequently, we have not been able to obtain detailed information as to the operative findings. But in none of the 15 cases was there any history of operation having been undertaken for the removal of fibroids or other organic disease of the pelvic organs. The story which we obtained was more or less the same in all cases. The patients had complained of menorrhagia for varying periods and had had the usual treatment with ergot mixtures iron tonics and rest in bed. None of them had had thyroid extract. When the condition did not respond to any of these measures operation was advised as affording the only means of relief. We have also added to this table three cases in whom an organic pelvic lesion, ovarian cyst or fibroid or both, was known to have been present. All three patients were operated upon and the typical symptoms of myxœdema have since developed attention it deserves. Investigations during the last half century have been concerned rather with what may be called the chemical side Recent advances in our knowledge of the muscle reaction to stretch and postural tone have introduced new conceptions, some of which I have attempted to apply to the muscles concerned in respiration

By adopting the orthograde position man has, to some extent, altered the mode of action of his respiratory muscles In animals the mechanical act of respiration is carried out almost entirely by the diaphragm, the bony thorax being more concerned with the support of the weight of the body and forming a case for the lungs than with expansion of the latter In man, though the diaphragm remains the chief agent, the thorax is freed from its weight-supporting function and helps expansion.

Under certain circumstances which I have described, too great a part of the work of expanding the lungs is transferred to the thorax This involves abnormal work by some of the thoracic muscles, a response which is ontogenetically unnatural to them and which qua muscle circulation and general energy is uneconomical Within limits they function without complaint, but with greater stimuli they are driven into conditions of persistent and excessive tonus These unnatural actions acquired comparatively recently cause symptoms, thus following the usual law Their protest takes the form of pain and distress These symptoms can be relieved by the removal of the source of the stimulus, or by relieving the stress on the muscle by mechanical means

Considering the general importance of the orthograde habit as an original cause of these troubles, and the influence of increased emotional development, we are forced to conclude that to a large extent these symptoms are among the penalties man pays for his advances over the lower animals

I have to acknowledge my indebtedness to Dr Wiltshire for helping me compose these lectures, and to the Medical Research Council for a grant in 1919 towards the recording apparatus

MENORRHAGIA AS A SYMPTOM OF MYXŒDEMA.

BY H. GARDINER-HILL, M B CAMB, M R C P LOND,

AND

J FOREST SMITH, M R C P LOND.

(From the Medical Unit, St Thomas's Hospital)

THE frequency of menorrhagia as a symptom of myxœdema is now quite generally recognised by those who have studied myxœdema from the clinical aspect, but it has scarcely received sufficient attention in the text-books of gynæcology In the present instance we have analysed the menstrual histories of 59 cases of myxœdema seen by us during the past five years. The results show quite clearly that when myxœdema develops before the menopause it is usually accompanied by menorrhagia On the other hand, a considerable proportion of patients develop this disease *after* the menopause, either natural or artificially induced, and this may account for the impression that it is often accompanied by amenorrhœa

Summary of the Literature.

The following are the main facts which we have extracted from the literature bearing on this subject Most text-books of gynæcology state that myxœdema is accompanied by amenorrhœa, but Eden and Lockyer (1920) discuss the subject more fully and conclude that in the present state of our knowledge the relation of thyroid activity to uterine hæmorrhage cannot be defined. They point out that menorrhagia, without a recognisable local cause, is sometimes seen in women *suffering from myxœdema*, but that amenorrhœa is also found The occurrence of menorrhagia in myxœdema was first reported in 1893 by three separate observers, Allen Starr, Kirk, and Schotten, quoted by Meyers and Falta Later Murray (1908) pointed out that although menorrhagia occurred during the early stages of myxœdema in some cases, amenorrhœa was more commonly found Sehrt (1913), quoted by Novak, reported a series of 55 cases of functional hæmorrhage In 38 of these cases there were definite indications of hypothyroidism Hertoge (1915) suggested *that the profuse* menstruation of thyroid-deficient women was due to infiltration of the uterine muscle and mucosa and to diminished coagulability of the blood He also pointed out that the higher the degree of thyroid defect the greater was the menstrual loss McCarrison (1918) was *also* of the opinion that menorrhagia is a sign of thyroid deficiency and that it is the rule when thyroid defect arises in later life, the menstrual period being prolonged and the intervening time shortened Finally, Israel Bram (1924), in his book on goitre, summed up the *existing evidence* and *gave* it as his opinion that though menstruation in thyroid deficiency is often regular in rhythm, it is usually excessive and characterised by menorrhagia The association of menorrhagia with thyroid deficiency has, therefore, been frequently described

Cases occurring before Natural Menopause

Table I shows a series of 23 cases in whom myxœdema developed before the natural menopause The average age of the menopause in women in this country is, of course, variable but it is generally taken as occurring between the ages of 45 and 52 In half the cases of this group the patients had not reached the menopause when seen by us for the first time In the remainder the history showed that the menopause had occurred at the average age (the average *for the* 11 cases was 48½), and had been preceded by menorrhagia, generally of two or three years' duration The basal metabolic rate was estimated in the majority of these patients and in all those so examined it was considerably below the

Indications for Treatment at Various Stages.

At a very early stage of the disease—that is to say, within the first few weeks of the recognition of the attack—the most important indication by far is to place the paralysed muscles at complete rest. Further, they must be rested in a position of complete relaxation The most effective splint for this purpose is a plaster bed, which consists, really, of a suitably-padded plaster case in which the patient lies completely immobilised This not only affords the best possible prospect of recovery of function in the injured muscles, but also minimises the pain which is not infrequently quite considerable at this stage

Complete physiological rest of the affected muscles is at this stage incomparably more valuable than massage, movements or electricity. Indeed, it is generally unwise to employ these measures at this stage Even at a later date, electricity is far less valuable than is often imagined If it were necessary to choose between efficient splintage and electricity, the choice should undoubtedly fall in all cases upon splints Electricity is at best but a poor substitute for the natural stimulation of the paralysed muscles and the greatest care and skill must be employed in its application; in particular, care must be taken that only the paralysed muscles are stimulated to contract and that the current does not overflow into the opposing and probably normal muscles, or else the effect produced will be the exact opposite of that which is desired—viz, the opposing muscles will be strengthened whilst the paralysed muscles will be still further weakened by the strain to which they are subjected Again, care has to be taken not to make the weakened muscles work against an over-great resistance lest they should be exhausted, and they must not be exercised to the point of fatigue; the object is to strengthen them and not to weary them It is unwise, in my experience, to prolong the systematic use of electricity for more than a year As a rule young patients become rather current-shy by the end of this time and a certain amount of voluntary power will then have returned in muscles destined to recover, on the other hand, if the muscles are not going to recover, no good will come from further prolongation of the electrical treatment As soon as a certain amount of voluntary power has returned in the paralysed muscles, voluntary movements performed by the patient himself, manually assisted if necessary, will be quite as effective as electrical stimulation and probably better.

The gist of this is that electrical stimulation is a valuable aid at a certain stage and so long as it is suitably carried out; but it is always to be regarded as an adjunct to treatment The promiscuous use of a faradic battery by ignorant parents and others is to be whole-heartedly condemned

Cause of Contractures

The contractures that take place in infantile paralysis are due to two causes—viz, the unbalanced action of the muscles and the effect of gravity. For example if the extensor muscles on the front of the leg are paralysed and the calf muscles are not, the latter muscles will pull the heel up and the foot down and the deformity known as talipes equinus will result Gravity aids in the production of this deformity, because the natural tendency of the foot, if unsupported by the extensor muscles, is to drop down by its own weight. It is of prime importance to prevent this equinus developing, not only because it renders walking difficult and a subsequent tenotomy for its relief necessary, but also because it takes away practically all hope of recovery in the damaged extensor muscles

I cannot emphasise too strongly the importance of always protecting the paralysed muscles from over-stretching, which is the first and most fundamental law of successful treatment. If it were only appreciated more widely, the sum total disability from infantile paralysis would be approximately halved. It is still quite a common experience to see children in orthopædic clinics who have been treated with electricity and perhaps massage for several years, but have never had a splint applied from the very onset of their disease. In infants, and in quite early stages of paralysis in older children, night-splints only will be needed, but when the power of walking begins to return it will probably be necessary to provide a day-splint as well, designed to assist the action of the weakened muscles Incidentally, it may be remarked that the most striking deformities are produced when certain muscle-groups are only affected; if one muscle pulls and its opponent does not pull, the foot will obviously be dragged out of its normal position, whereas if all the muscles of a limb are more or less equally paralysed no gross deformity will ensue, though the limb may be practically flail.

Indications for Operation

In considering the advisability of operation one of the first questions will be. *At what age should it be undertaken?* Much depends, of course, upon the nature of the operation that is contemplated, but it may be stated as a generalisation that it is unwise to perform any sort of operation within about three years of the onset of the attack. Usually, if treatment has been adequate in the meantime, no operation is necessary at such an early date, but the main point is that recovery may still take place, in greater or less degree, within this period; generally, of course, the greatest amount of recovery takes place in the early months following the onset, but it goes on more slowly for many months afterwards and in some cases seems to appear quite unexpectedly after months of apparent failure of response to treatment It can hardly be said, therefore, within three years of the onset, what the ultimate paralysis is going to be, and many surgeons would defer the decision until five years or even later. The only operation that should be performed, in my opinion, within this period, is simple tenotomy—usually tenotomy of the tendo Achillis In cases in which a proper rectangular night-splint has not been applied, an equinus deformity may appear, and this renders walking very difficult and greatly decreases the prospect of recovery of the affected extensor muscles; in such cases the calf-muscles soon undergo contracture, and when this has occurred it is unsatisfactory to attempt to stretch them again by splintage and the most practical way of treating the condition is to perform tenotomy of the tendo Achillis In several of these cases, in which there has not been the least response to efficient treatment whilst the equinus persisted I have obtained practically complete recovery after relaxing the extensor muscles by performing tenotomy.

At a later stage the question of an operation may be considered from various points of view · (1) We can never create power, for those muscle-fibres that have been destroyed by the disease are permanently destroyed, and the utmost that conservative treatment can achieve is the development of the fibres that remain. Such power as is gone is gone for ever. But where the damage has been unbalanced in its distribution we can sometimes redistribute the power, with resulting improvement in function. (2) If the muscles controlling a joint have been so extensively damaged that the joint is practically "flail," that joint becomes a hindrance instead of a help, and the patient would be better without it (3) An operation may enable the patient to dispense with the use of apparatus, or at any rate to get along with an instrument which is cheaper, less cumbrous, and less expensive than formerly (4) In neglected cases considerable contractures often appear and serious mechanical disability is then invariably added to that which results from the paralysis per se. A judicious correction of the mechanical disability by division of contracted muscles, ligaments, joint capsules, &c will then substantially improve function We will consider each of these headings in turn.

TABLE IV.—*Myxœdema Developing after Artificial Menopause.*

Case	Present age	Type of operation	Age at operation	Operation for—	Alteration in weight since operation	Present condition—B M R or sugar tolerance

18*	57	Double ovariotomy hysterectomy (fibroid)	50	„	+2 st 4 lb	Typical myxœdema

* With additional ovarian cyst or fibroid.

In the majority of the patients of this group the basal metabolic rate was estimated and found to be considerably below the normal The results are given in Table IV In the others this examination could not be made, but the typical symptoms of myxœdema were present in all Four of the patients showed the typical decrease in sugar tolerance which we, in association with P C Brett, have already reported as a characteristic change in myxœdema Taking into consideration the facts which we have already quoted in Table I, it has seemed probable to us that in some of the patients of this group (Table IV) at any rate the menorrhagia which occurred before operation was an early symptom of myxœdema This suggestion is supported to some extent by the subsequent development of characteristic symptoms of myxœdema in all In the absence, however, of more accurate information as to the condition of these patients before operation, this view can only be regarded as hypothetical Nevertheless, the cases reported in Table I do show that in this series a very definite proportion of women suffering with menorrhagia are the subjects of some degree of hypothyroidism And what we particularly wish to emphasise as a result of these observations is that where pelvic examination reveals no abnormality, the possibility of thyroid deficiency should always be raised. Investigation of the basal metabolic rate is useful in this connexion

Summary and Conclusion

As a result of the analysis of the menstrual history of 59 cases of myxœdema the following conclusions have been reached (1) In our series of cases myxœdema developed before the natural menopause in 56 per cent and after the menopause in 44 per cent (2) When myxœdema developed before the natural menopause menorrhagia was present in 78 per cent of cases (3) Myxœdema is a common sequel to the artificial menopause when the latter has been induced for menorrhagia without apparent local cause Fifteen cases have been quoted in this paper The probability is that the menorrhagia, in some of these patients at any rate, was an early symptom of myxœdema

In conclusion, we wish to express our thanks for the help which Prof H MacLean has extended to us, and to the Medical Research Council for defraying expenses for this investigation

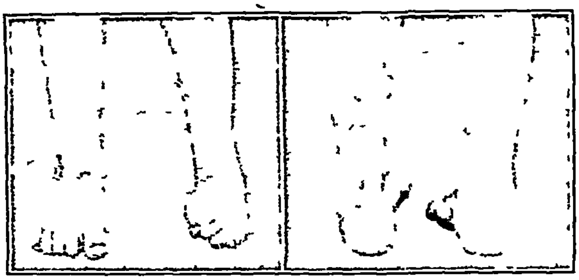
ORTHOPÆDIC SURGEON, CROYDON GENERAL HOSPITAL, AND WEST KENT GENERAL HOSPITAL, SURGICAL SPECIALIST FOR THE ROYAL AIR FORCE

CASES of infantile paralysis are not of everyday occurrence in general practice, and it would be unreasonable to expect the average family doctor to possess a full and critical knowledge of all the operations that have been devised for the relief of this condition But it is most emphatically the duty of every practitioner to know what can and cannot be achieved by various methods of treatment, and especially by operative treatment, so that his patients may not endure any unnecessary suffering In other words, he should know enough about present-day practice in the treatment of infantile paralysis to be able to give his patient the benefit of the most modern forms of treatment Furthermore, he must be sufficiently skilled in the management of the case in its non-operative stage, to prevent any avoidable increase of disability, in particular he must not allow any contracture of the paralysed limbs and must avoid any increase of the existing paralysis from overstretching of the paralysed muscles The main object of this paper is to indicate what expert orthopædic surgery can offer for the relief of certain types of paralytic cases and to avoid details of interest only to the actual operator vehicles, and so on Many surgeons, therefore, think that it is better to provide a hinged instrument which can be locked at will.

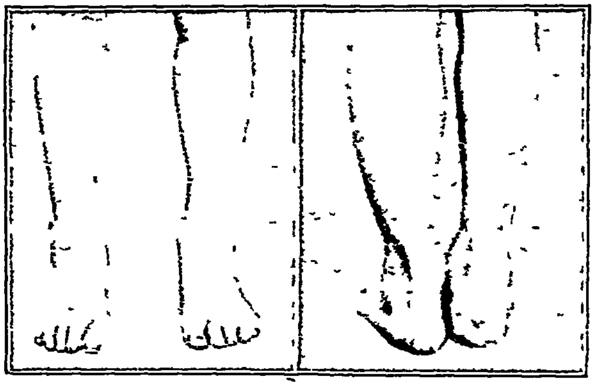
The shoulder, however, when paralysed, provides an ideal opportunity for the performance of arthrodesis As a rule, when the deltoid is paralysed the rest of the limb is fairly serviceable, but as the shoulder-joint forms a loose and-uncontrollable link between the upper extremity and the trunk, the arm, though it may be perfectly good in itself, is rendered functionally useless By ankylosing the arm at right angles to the glenoid cavity an enormous improvement is immediately obtained, for the patient is able to move the upper limb with the scapula to quite a useful extent by means of the scapular muscles

FIG 3 A



Before operation.

FIG 3 B



After operation

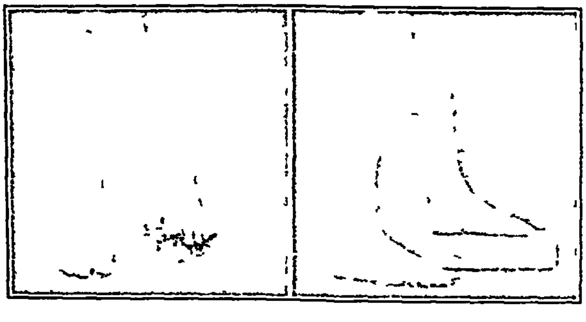
Another tendon transplantation, before and after operation

In the case of flail foot and of feet which are too severely paralysed to be amenable to treatment by means of tendon-transplantation, arthrodesis is now becoming largely replaced by the more modern stabilisation operations For the most part these consist in a combination of partial arthrodesis with mechanical rearrangement of the foot so as to render it a firmer basis upon which to balance the body-weight when walking For instance, the fore-part of the foot may be shortened by removing bone, so that the anterior pillar and the posterior pillar, as seen from the side, are more nearly equal in length and approximate more closely the form of an equilateral triangle A common method nowadays is to ankylose the subastragaloid and the mediotarsal joints and to leave the ankle-joint untouched Even though the muscles of the leg be completely paralysed it is still possible for the patient to balance upon the ankle-joint, much as a person balances on the ankle-joint of an artificial limb , and this method gives a much more elegant gait than does the older operation of panarthrodesis The operation which I prefer to all others for the stabilisation of a flail foot or a much paralysed foot consists in a combination of the methods introduced by Naughton Dunn and Hoke By this method a stable foot can be produced in practically any case of advanced paralysis of the muscles of the leg and with simultaneous rectification of any gross deformity that may have crept in in the course of years Of course, if shortening is present that persists, but patients always regard it as the greatest boon to be able to get rid of their leg-irons and to have to wear only a high boot or shoe which indeed may hardly attract attention if the shortening be moderate and capable of being compensated by a cork inlay inside the footwear

Even in cases where there is considerable paralysis of the thigh, in addition to a flail foot it is still worth while to perform a stabilisation operation for the flail foot because this rids the patient of the preponderating factor in the instability of his limb, and his gait becomes proportionately improved , further he can often use a light knee-cage instead of a heavy double instrument reaching from the ground to the thigh, and in any case the cure of the drop-foot usually results in a great saving of expense in respect of surgical boots Fig 4 shows a very interesting case of infantile paralysis treated by arthrodesis

Arthrodesis and stabilisation operations depend for their success upon sound bony fusion between the bared bone surfaces, and are, therefore, best performed when the tarsal bones are fairly well ossified , they can be carried out successfully at 9 years, but it is better whenever possible, to postpone the operation until a few years later. In other words, cases of flail foot and severely paralysed foot are best treated by instruments, as a rule, until they are 10 to 12 years of age, when a Dunn-Hoke or some similar operation can be carried out with very great advantage These patients appreciate enormously the knowledge that when once this operation has been carried out their foot has been stabilised once for all and that it can never get out of shape again, and that they have henceforward only to concern themselves from time to time with the provision of a new boot with a concealed inlay Knowing that they will not be liable for the future to have to enter hospital again from time to time and that if they get a wage-earning post they will be able to keep it, these patients find their outlook on life wholly altered and they gladly seek remunerative occupations

FIG. 4



A stabilisation operation

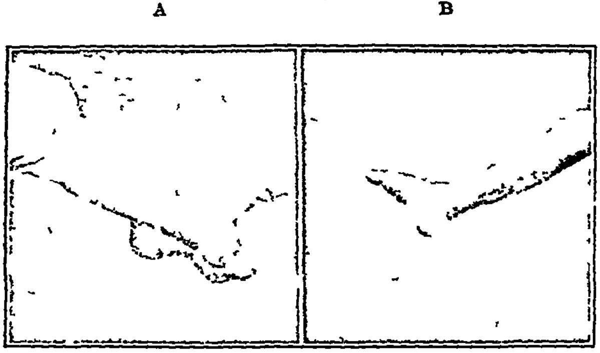
Myotomies and Capsulotomies

In neglected cases, when the proper use of splints has been lacking, contractures often occur, and a considerable mechanical disability is added to that which has already been produced by the paralysis itself For example if a calliper is outgrown the knee will flex and this will result secondarily, in a flexion at the hip-joint in order to maintain the erect attitude In some cases it is even found that patients have been kept in bed for unnecessarily long periods and the use

Tendon Transplantation.

If one important muscle is seriously paralysed, and another good muscle of similar action is available and can be spared from its present position and function its tendon may be detached from its present insertion and transferred to that of the paralysed muscle This is the fundamental principle of tendon transplantation Generally speaking, it may be taken as axiomatic that the tendon to be transplanted should be that of a muscle of homologous group—that is to say, that a flexor tendon should be transplanted into a flexor and an extensor into an extensor, and not vice versa Further, the surgeon has to beware of the obvious fallacy of " robbing Peter to pay Paul ", a tendon must only be transplanted if its function can be substituted, in greater or less degree, by some means or other, and if it is going to subserve a more important function in its new position than it did in its normal one Lastly, it is obviously useless to transplant a tendon unless the muscle belonging to it is of adequate power, if it cannot do its work efficiently in its new position it is much better to treat the case by instruments or some other means For example, if all the muscles of a leg have suffered severely and none of them retain much power, it is not much good to perform transplantation, even though one group be rather more powerful than another which it is desired to reinforce It must be borne in mind, too, that it is not enough for a transplant to be capable of effecting a certain movement of a bare foot resting upon a pillow What it has to do is to effect the movement when the limb is carrying the body-weight, which is a very different proposition, and in many instances it is a question of carrying, not only the body-weight, but also the weight of a high boot, which may be considerable I can recall several cases where this important practical point was overlooked and a tendon-transplantation which looked perfectly satisfactory when the patient lay in bed was found to be perfectly unsatisfactory in practice

FIG 1.



A, Paralytic talipes calcaneo valgus Gastrocnemii and soleus seen, at operation, to be totally destroyed

B, Result of tendon-transplantation

The ideal case, then, for tendon-transplantation is that in which one important muscle-group is severely paralysed, a fair amount of power remaining in the limb generally, and another sufficiently homologous muscle is available for the substitution of the damaged one

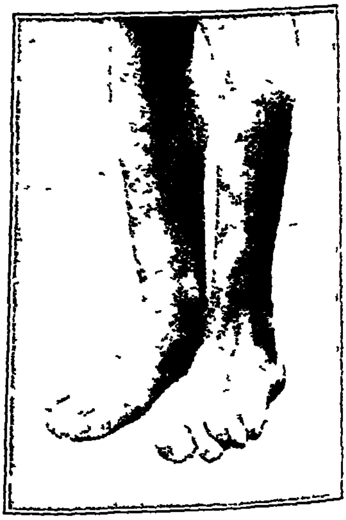
Two good examples of helpful tendon transplantation are (*a*) the substitution of a paralysed calf-muscle by the use of the peronei and toe-flexors Fig 1 shows a patient in whom the calf-muscles were found at operation to be totally destroyed, consisting of a mere tissue of white fat and fibrous material, tendon transplantation was performed and the second photograph shows the result The patient was able to walk about, run, and stand on tip-toe without instrumental assistance (*b*) The substitution of paralysed tibiales (which results in the production of a very disabling paralytic valgus) by the use of both long extensors of the toes; it is true that a certain amount of power of extension of the ankle-joint is lost by this means, but it is not entirely lost and extension of the toes can still be performed by the extensor brevis If a choice has to be made of the lesser of two evils, it is found in practice to be far better to sacrifice a slight amount of extension in order to be cured of a painful and unsightly valgus.

One of the most successful of the simpler transplants is that of the tibialis anticus to the outer border of the foot for the relief of peroneal paralysis, this operation is valuable in Friedreich's paralysis and various other nerve lesions, as well as in infantile paralysis (Fig 2)

Many other examples of tendon-transplantation might be given, but the above will suffice to illustrate its usefulness (Fig 3)

One particular transplantation may be mentioned, however, because, though it seems to be opposed to theoretical principles, it nevertheless gives satisfactory results This is the transplantation of the biceps cruris to assist the action of a weakened quadriceps This is an example of a heterotype transplantation—that is to say, it consists in the substitution of an extensor by a flexor muscle But in some cases in which the quadriceps is just too weak for its work, and there is a slight amount of instability of the knee it is found that the reinforcement of the quadriceps by carrying forward the biceps muscle and tendon gives just that slight increase in power which is sufficient to stabilise the joint In suitably selected cases this operation may enable the patient to dispense with an unsightly and expensive splint, reaching to the groin, or, in hospital cases, to get rid of an awkward calliper splint

FIG 2



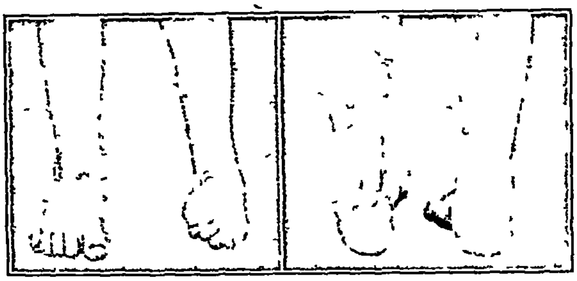
Tibialis anticus transplanted to outer side of foot (Useful in many forms of talipes varus one of the most efficient of transplantations) The case shown is one of Friedreich's disease

Stabilisation Operations

When a joint is wholly uncontrollable it is clearly a nuisance. It can be stabilised in one of two ways—viz , either (*a*) by the use of an instrument furnished with a hinge which can be locked at will, or (*b*) by removing the articular cartilages by operation and producing a bony ankylosis instead of a joint This type of operation is known as an arthrodesis In many cases of infantile paralysis it is very valuable For example, in the case of a flail foot there are quite a number of uncontrollable joints—viz , the ankle-joint, the subastragaloid joint, and the mediotarsal joint To control such a flail foot it is necessary for the patient permanently to wear an instrument consisting of double steels reaching to the knee or else to have the joints fixed by operation This results in rather a " clumping " walk, but many patients much prefer this to the permanent wearing of a heavy, clumsy, expensive, and unsightly apparatus A flail knee also, can easily be stabilised by the performance of arthrodesis, but it is a debatable question whether this operation is preferable to the use of a knee-cage, for though an arthrodesis may deliver the patient from the wearing of an apparatus, it leaves him with a very awkward limb which gets greatly in the way in public vehicles, and so on Many surgeons, therefore, think that it is better to provide a hinged instrument which can be locked at will

The shoulder, however, when paralysed, provides an ideal opportunity for the performance of arthrodesis As a rule, when the deltoid is paralysed the rest of the limb is fairly serviceable, but as the shoulder-joint forms a loose and uncontrollable link between the upper extremity and the trunk, the arm, though it may be perfectly good in itself, is rendered functionally useless By ankylosing the arm at right angles to the glenoid cavity an enormous improvement is immediately obtained, for the patient is able to move the upper limb with the scapula to quite a useful extent by means of the scapular muscles

FIG 3 A



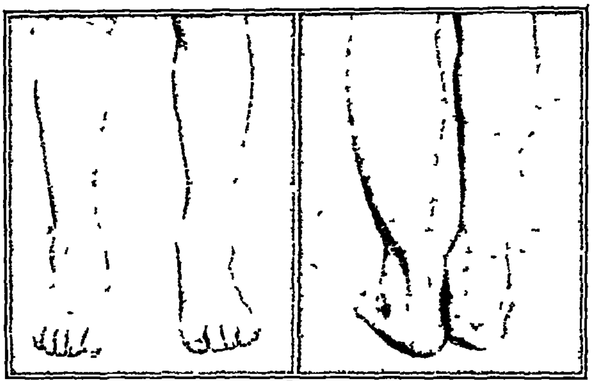
Another tendon transplantation, before and after operation

Before operation

In the case of flail foot and of feet which are too severely paralysed to be amenable to treatment by means of tendon-transplantation, arthrodesis is now becoming largely replaced by the more modern stabilisation operations For the most part these consist in a combination of partial arthrodesis with mechanical rearrangement of the foot so as to render it a firmer basis upon which to balance the body-weight when walking For instance, the fore-part of the foot may be shortened by removing bone, so that the anterior pillar and the posterior pillar, as seen from the side, are more nearly equal in length and approximate more closely the form of an equilateral triangle A common method nowadays is to ankylose the subastragaloid and the mediotarsal joints and to leave the ankle-joint untouched. Even though the muscles of the leg be completely paralysed it is still possible for the patient to balance upon the ankle-joint, much as a person balances on the ankle-joint of an artificial limb , and this method gives a much more elegant gait than does the older operation of panarthrodesis The operation which I prefer to all others for the stabilisation of a flail foot or a much paralysed foot consists in a combination of the methods introduced by Naughton Dunn and Hoke By this method a stable foot can be produced in practically any case of advanced paralysis of the muscles of the leg and with simultaneous rectification of any gross deformity that may have crept in in the course of years Of course, if shortening is present, that persists, but patients always regard it as the greatest boon to be able to get rid of their leg-irons and to have to wear only a high boot or shoe, which, indeed, may hardly attract attention if the shortening be moderate and capable of being compensated by a cork inlay inside the footwear

Even in cases where there is considerable paralysis of the thigh, in addition to a flail foot, it is still worth while to perform a stabilisation operation for the flail foot, because this rids the patient of the preponderating factor in the instability of his limb, and his gait becomes proportionately improved , further, he can often use a light knee-cage instead of a heavy double instrument reaching from the ground to the thigh, and in any case the cure of the drop-foot usually results in a great saving of expense in respect of surgical boots Fig 4 shows a very interesting case of infantile paralysis treated by arthrodesis

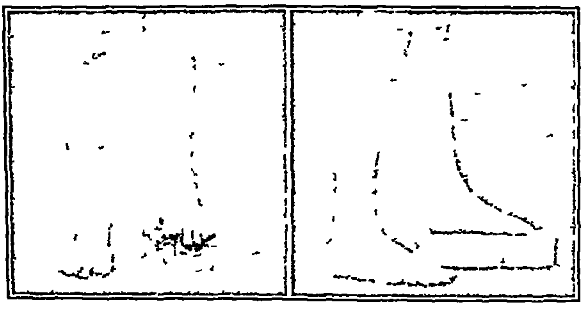
FIG 3 B



After operation

Arthrodesis and stabilisation operations depend for their success upon sound bony fusion between the bared bone surfaces, and are, therefore, best performed when the tarsal bones are fairly well ossified , they can be carried out successfully at 9 years, but it is better, whenever possible, to postpone the operation until a few years later In other words, cases of flail foot and severely paralysed foot are best treated by instruments, as a rule, until they are 10 to 12 years of age, when a Dunn-Hoke or some similar operation can be carried out with very great advantage These patients appreciate enormously the knowledge that when once this operation has been carried out their foot has been stabilised once for all and that it can never get out of shape again, and that they have henceforward only to concern themselves from time to time with the provision of a new boot with a concealed inlay Knowing that they will not be liable for the future to have to enter hospital again from time to time, and that if they get a wage-earning post they will be able to keep it, these patients find their outlook on life wholly altered and they gladly seek remunerative occupations

FIG 4



A stabilisation operation

Myotomies and Capsulotomies

In neglected cases, when the proper use of splints has been lacking, contractures often occur, and a considerable mechanical disability is added to that which has already been produced by the paralysis itself For example, if a calliper is outgrown the knee will flex and this will result, secondarily, in a flexion at the hip-joint in order to maintain the erect attitude In some cases it is even found that patients have been kept in bed for unnecessarily long periods and the use of pillows beneath the knees and behind the shoulders has resulted in the production of flexion at both these joints All the structures upon the concavity of the joint become contractured, not only the muscles The latter can be easily stretched by means of weight extensions, but joint-capsules are made of very tough white fibrous tissue and are very resistant to the stretching process and very liable to relapse as soon as the weight is removed A much more rapid and much more workmanlike method than stretching is the open division of all the resisting structures, including the joint-capsule This method, not being prone to relapse, is to be preferred in all cases, and especially in those cases of relapse due to parental neglect, since the result is much more likely to be permanent than is the result of temporary weight-extension The method is particularly applicable in the case of contracture at the knee, but can also be applied in the case of other joints—e.g, the hip and the elbow At the hip it is usually necessary to divide all the muscles upon the front of the hip-joint and the anterior part of the capsule of the hip-joint itself, avoiding only the anterior crural nerve and the great vessels In cases of extreme deformity it is often necessary to correct the faulty position of the limb by stages It is easy to obtain sufficient lengthening of the muscles, ligaments, and joint-capsule at one sitting, but there would be danger to the nerve-supply and circulation of the limb if the contracture were corrected at once, it may be necessary, therefore, after division of all possible structures, to bring the limb down to a certain extent only and to fix it there in plaster for a few weeks before undertaking a further correction. By proceeding in this way even the severest cases of neglected deformities can, as a rule, be remedied, including those distressing examples of four-footed progression

Amputation

Amputation is very seldom required nowadays in infantile paralysis The fact that a whole limb is totally flail is no justification for amputation, for, as Murhead Little pointed out, the last state may well be worse than the first if the patient is left with a stump which he is wholly unable to control and which is utterly different in use from the strong and perfectly controllable stump that carries the artificial limb in any ordinary case of amputation for trauma

It is well to remember that any patient can be made to walk somehow—perhaps not well, but still to walk—provided that he has one good buttock; even though one limb be totally flail and the other be severely paralysed he can still be made to walk after a style Only when both buttock muscles are completely paralysed and the legs are disconnected, so to speak, from the trunk is a patient incapable of being made to walk with the aid of instruments and operation Flail paralysis, per se, is not an indication for amputation Neither is the presence of severe contracture, for this can be remedied by capsulotomy, combined, if necessary, with arthrodesis or some other method of stabilisation Practically speaking, the principal indication for amputation in infantile paralysis to-day is the presence of inveterate ulceration of the affected limb Even so, every method of conservative treatment should have been exhausted and the capacity of the patient to control an artificial limb if amputation is performed should be most thoroughly considered before the operation is advised

---

W H LANGLEY MEMORIAL PRIZE —Applications are invited for the prize founded in memory of Dr W H Langley, C M.G, principal medical officer of Southern Nigeria The prize, which is of the value of £30, may be awarded triennially to an officer of the West African Medical Staff, whether on the active or retired list, for the best paper on (*a*) tropical medicine or surgery, (*b*) tropical hygiene and sanitation, or (*c*) tropical entomology and parasitology The award is made by a committee nominated by the London School of Hygiene and Tropical Medicine, Malet-street, W C 1, and papers should be sent in before Oct 1st Further particulars may be had from the Secretary of the school.

SUPPURATIVE THYROIDITIS.

REPORT OF TWO CASES

BY LAMBERT ROGERS, F.R C S EDIN,
ASSISTANT IN THE SURGICAL UNIT, THE WELSH NATIONAL SCHOOL OF MEDICINE, THE ROYAL INFIRMARY, CARDIFF

ALTHOUGH a rare condition, suppurative thyroiditis occurs in both sexes and at all ages It is most frequently seen, however, in adult women and may arise either in a previously normal thyroid or in a goitrous gland Continental writers distinguish inflammation of a previously healthy thyroid from inflammation of a goitrous gland by the terms thyroiditis and strumitis, and so speak of either suppurative thyroiditis or suppurative strumitis, but this distinction is not as a rule made by English writers Not all inflammatory conditions of the thyroid go on to suppuration.

As a rule there is not much difficulty in diagnosis. Following an acute specific fever, or an attack of boils, a swelling appears in the region of the thyroid, the overlying skin becomes hot and reddened, and the temperature and pulse-rate increase. The signs and symptoms of thyrotoxicosis may arise but if extensive destruction of the gland occurs these may be replaced (later) by those of hypothyroidism One or both lobes of the gland may be affected

The condition is very painful because of the numerous coverings of fascia which prevent rapid distension of the gland It will be remembered that between the capsule of the thyroid gland and the skin there are no less than five layers of fascia—the pretracheal sheath, the double layer of fascia enclosing the omohyoid muscles, the vaginal layer encasing the sternomastoids and further back the trapezius muscles, and the superficial fascia with the platysma Inflammatory adhesions produced between these layers of fascia may mask the fact that the swelling is in the thyroid gland, by preventing the usual up and down movement with deglutition, a movement which normally depends upon the fact that the pretracheal tube of fascia which encloses the gullet, the trachea and the thyroid, moves freely inside the omohyoid fascia The intrafascial tension may give rise to dyspnœa and dysphagia

Kocher (1878) was the first to point out that acute thyroiditis was due to metastasis of an infective agent elsewhere in the organism.

Pathogenesis.

Thyroiditis may arise —

1. By direct infection, the result of penetrating wounds of the thyroid gland These cases are apparently rare

2 By contiguity. The infection spreads from a focus in the vicinity as in the following —

A railway porter, aged 31, complained of a painful swelling of his neck His past health had been good but he had recently suffered from boils and examination revealed one just above the left sternoclavicular articulation The left lobe of the thyroid was enlarged and tender, the skin over it red, hot, and fluctuant, and his temperature 100° F A diagnosis of suppurative thyroiditis was made and under ether anæsthesia the left lobe incised and drained. Several ounces of yellow pus escaped For some months afterwards a sinus existed but this ultimately healed

3 By the blood stream This method of infection is illustrated by the following case —

A housemaid, aged 48, was admitted to a medical ward under the care of Prof A M Kennedy because of general weakness following influenza She had suffered from a toxic goitre for many years, and the left lobe of the thyroid had been larger than the right, but about the time of admission both lobes had begun to enlarge She developed acute pain in the neck and slight dyspnœa. Examination showed that the lower part of the neck was much swollen (see Fig) The skin over the thyroid gland was hot, reddened, and tender There was no movement of the swelling on deglutition A radiogram showed very marked displacement of the trachea to the right Suppurative thyroiditis was diagnosed and under gas and oxygen anæsthesia 10 oz of pus were evacuated from the thyroid

Influenza, as in this last case, is liable to give rise to suppurative thyroiditis; other causes of a hæmatogenous infection are scarlet fever, typhoid or puerperal fevers, pneumonia, tonsillitis, gastro-enteritis, cholera, dysentery, measles, malaria, acute rheumatism, and mumps. Thyroiditis due to rheumatism, malaria or measles however, does not, as a rule, proceed to suppuration, while that following influenza or typhoid, scarlet or puerperal fever, frequently does.

Bacteriology.

The organisms commonly found in the pus are staphylococci or streptococci, or the *Bacillus coli*, but paratyphoid A and B infections have been recorded by French writers. The organism in the postinfluenzal case reported here was a Gram-positive diplococcus of a chain-forming type, which produced colonies resembling those of the streptococcus. De Quervain believes that suppuration more often follows infection of thyroids containing goitrous nodules than of previously healthy or diffusely hypertrophied glands. He also draws attention to the important fact that chronic suppurative thyroiditis, whether starting in a healthy or diseased gland, is nearly always tuberculous.

Treatment.

The treatment of acute suppurative thyroiditis, like that of suppuration elsewhere, is evacuation of the purulent contents and drainage. André Crotti relates the story of the distinguished surgeon, P. Franck, who when a small boy suffered from suppurative thyroiditis from which he nearly lost his life, "because the best physician in the district pompously declared that the child had ruptured a nerve in his neck and that death was imminent." Franck's mother, however, thinking that the swelling in her son's neck had something to do with his choking, called in a barber and told him to incise the swelling with his razor. Immediately a great quantity of pus gushed out and the dyspnœic symptoms ceased. The fistula which afterwards existed closed spontaneously after seven years.

In those cases in which when first seen the skin is beginning to soften and the pus point, all that is necessary is to make an incision in this area and establish drainage. It is not advisable, however, to wait until the condition has advanced so far, but is better to make a small incision in one of the lower crease lines of the neck, if necessary to ligate and cut the anterior jugular veins or their branches, split and retract the sternothyroids, and expose the capsule of the gland. At this stage, an aspirating syringe is useful; when pus is found the needle track is incised and dilated with sinus forceps. A small glass or rubber drainage-tube is inserted into the abscess cavity. In the latter of the two cases here referred to each lobe was drained in the way described, the two tubes leading out through a small incision, *en cravat*. Between the tubes from the gland a shorter tube was passed down to the cellular tissue of the neck. The wound was healed by the fourteenth day, but the patient subsequently suffered from thyrotoxicosis for which ligation of both superior and the right inferior thyroid arteries was performed in stages.[1]

Dyspnœa in these cases is very rarely sufficiently extreme to demand tracheotomy, the relief of tension in the gland by evacuation of its purulent contents sufficing to relieve the pressure on the trachea. If a sinus persists this may be due to the presence of calcareous nodules in the thyroid, and partial extirpation of part of the gland may be necessary when the inflammatory condition has become quiescent. Suppurative thyroiditis presents no great difficulty either in diagnosis or treatment, but its rarity is well illustrated by an annotation in THE LANCET of Jan. 29th, 1927, in which reference is made to a paper by Dr. H. M. Clute and Dr. L. W. Smith, of the Lahey Clinic and Pathological Department of the Harvard Medical School. Out of 3000 thyroid operations performed in this clinic only three were for suppurative thyroiditis.

Clinical and Laboratory Notes.

TWO CASES OF ADVANCED CARCINOMA OF THE STOMACH

By BEATRICE TURNER, M.B. LOND., M.R.C.S. ENG.,

HOUSE SURGEON TO THE CANCER HOSPITAL, LONDON.

IN view of the efforts at present being made to ensure earlier diagnosis of cancer, these two cases may be of interest.

CASE 1.—A man, aged 42, a pilot, was admitted on August 17th, 1925, complaining of pain in the left hypochondrium. He stated that 12 months ago he had begun to notice a feeling of fullness with occasional momentary pain in left side. This occurred about every second day and had no relation to food. As from February, 1925, he had noticed slight loss of weight, and had been to several doctors. In July, 1925, he saw Sir John Bland-Sutton, who told him he had a new growth of the stomach and advised against operation.

On admission the patient was a sturdily-built, healthy-looking man with florid complexion. No definite relation could be established between the pain complained of and ingestion of food. He was able to eat large meals, including meat, with hearty appetite and enjoyment. Palpation failed to reveal the presence of a tumour, although Sir John Bland-Sutton had been able to detect the presence of one.

A blood count gave the following results: red cells 5,010,000, white cells 8800, hæmoglobin, 92 per cent. Radiography after a barium meal showed an irregular filling defect, involving the greater curvature in the pyloric end of the stomach; there was no delay in emptying, but irregular traces of the meal were left in the stomach at seven hours. The appearances suggested a new growth, probably extensive. A fractional test-meal showed diminished total acidity and almost complete absence of free hydrochloric acid. At operation on August 21st it was found that the anterior and posterior surfaces of the stomach in the prepyloric area were extensively invaded by new growth which had involved the omentum. Operative removal was out of the question, and the abdomen was closed.

CASE 2.—A man, aged 48, a farmer, was admitted on Jan. 11th, 1927, complaining of pain before meals and discomfort after. He said that six weeks ago he had begun to have pain in the epigastrium before meals, it was relieved by taking food and did not occur every day; it might be absent for two or three days at a time. His appetite had been good, his food consisted of an ordinary diet, and apart from the slight discomfort complained of, he had been objectively and subjectively in perfect health.

On examination he was a well-built, florid-looking man, and nothing abnormal could be detected in the abdomen, except definite tenderness which could be elicited by deep pressure in the epigastrium. A barium meal showed an irregular filling defect at pyloric end of the stomach. There was no delay in emptying, but suspicious flare remnants were seen at seven hours, and the appearances suggested a new growth. A fractional test-meal showed diminished total acidity and almost total absence of free hydrochloric acid

---

[1] This case was shown at a meeting of the Cardiff Medical Society at the Cardiff Royal Infirmary on Dec. 14th, 1926.

At operation on Jan 21st the stomach was exposed through a transverse incision dividing both recti, and was found to be the site of a large ulcer involving the anterior wall of its pyloric end No abnormally large glands could be detected, but the extensive infiltration of the surrounding stomach wall suggested that the condition was carcinomatous Partial gastrectomy was performed, with direct union of the jejunum with the cut end of stomach

A pathological report stated that the growth was a spheroidal-celled carcinoma, infiltrating the wall of the stomach The lymphatic gland selected for section was not involved

Convalescence was uninterrupted and the patient was discharged on Feb 14th

The special interest in these two cases lies in the almost complete lack of symptoms found in either of them Both patients looked extraordinarily healthy and there was no wasting or anæmia, no anorexia, and only very slight discomfort Very little could be found on examination In fact, without the aid of X ray and the laboratory, diagnosis would have been almost impossible The probability is that without the warning of Case 1, the second patient would not have been investigated until the condition was inoperable

For permission to publish these cases I am indebted to Sir John Bland-Sutton and Mr Percival Cole They were both under the care of Mr Cole at the hospital

THE USES AND LIMITATIONS OF CREAM IN INFANT FEEDING

BY DONALD PATERSON, M B EDIN, M R C P LOND,
PHYSICIAN FOR THE DISEASES OF CHILDREN, WESTMINSTER HOSPITAL, PHYSICIAN TO OUT PATIENTS, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

THE term " cream " is now applied in a wide sense and requires defining By " cream " may be meant (1) cows' milk or breast milk cream, or (2) synthetic cream, such as emulsions of cod-liver and other oils, known as Marylebone cream, New Zealand cream, and Vitoleum cream

Is there any particular value in high cows'-milk-cream-content in infant feeding ? Are whey-cream mixtures of great value ? Is very creamy dairy milk to be greatly sought after ? To answer these questions they must be considered from all sides If the infant be absolutely normal it takes such feeds and thrives on them That it thrives on them better than on less creamy foods, however, is a matter of debate Nevertheless, it does thrive There are numbers of infants, however, who are quite unable to manage a high fat-content in their feed, and possibly these represent 1 in 10 of the population To these infants such creamy mixtures are indigestible, they are not tolerated The fact that an infant thrives on a high fat diet is a guarantee of its normality Now let us consider the normal infant on this high fat diet when it is suffering from some mild or severe infection There is no doubt whatever that a severe degree of acidosis occurs in such a child as the result of its infection, and that this violent reaction would not occur if it were on a less ketogenic diet

The normal healthy infant may tolerate much fat during the cooler months of the year, but during the summer months, in a still atmosphere, a violent intolerance is apt to be shown if the food is pushed a little too far and the child urged over its bottle This bilious attack is less likely to occur if the child's diet is lower in cream Finally, the vitamin-content of milk varies with the season of the year and the food of the animal producing it In the winter months it has been shown that stall-fed cattle, much confined in dark stables, produce cream with extremely little vitamin[1] Probably on the whole then, the disadvantages of high fat feeding outweigh the advantages

Regarding synthetic creams, such as the various forms of cod-liver oil emulsion on the market and such creams as Marylebone cream, New Zealand cream, and vitoleum cream, another view must be taken That these creams are of great value to the infant apart from their vitamin-content is most debatable In other words, a good brand of cod liver oil emulsion, given in eggspoon doses, or a few drops of plain cod-liver oil three times daily immediately before feeds, is of as great value to the infant The nipple or teat should be placed in the baby's mouth at once, the cod-liver oil being washed down with the milk There are extremely few infants who do not tolerate minute doses of cod-liver oil if given in this way before their feeds. Many mothers complain that the food is vomited, but probably it is their own distaste for the oil which makes them administer it in a shrinking or awkward manner, causing the child to return it Putting the cod-liver oil in the bottle is useful, but it tends to remain behind on the sides of the bottle and in the teat itself When it is administered separately *after* the feed there is a danger, if it is awkwardly given, that the whole feed will be returned

To prolong feeding on milk—that is, feeding on an exclusive milk diet after six months—necessitates large quantities of milk being given This means, as a rule, a proportionate steady increase in the quantity of fat or cream being metabolised, and a tendency occurs in certain children to develop a chronic fat intolerance or inability to absorb the fat, known as cœliac disease Probably the greatest error made in feeding older infants and children is the too long continuance of the exclusive milk diet or the administering of milk in too large quantities

To conclude, therefore, quite sufficient fat or cream is present in an ordinary diluted cows' milk feed without any further additions Every infant, however, breast-fed or bottle-fed, should be given cod-liver oil in small doses from birth for its vitamin-content rather than for its food value

TWO CASES OF BUBONIC PLAGUE

BY H MERRICK BOSTON, M B, CH B LIVERP,
HOUSE PHYSICIAN, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

THE following cases will probably be of general interest by reason of the comparative rarity of bubonic plague in this country The second case was discovered accidentally, the man not having sought advice A brief report of the two cases appeared in THE LANCET of Sept 11th, 1926 (p 573)

CASE 1 —A boy, aged 10, was admitted to the David Lewis Hospital at 6 A M on August 28th, 1926, having complained of headache and nausea since the previous evening, during the night he had vomited several times, and towards morning had experienced short periods of delirium

On admission he appeared to have some abdominal pain, but there was no resistance or tenderness, except in the left groin, where there were enlarged glands which appeared painful on palpation The spleen was not palpable, nothing abnormal was found in the chest, the reflexes were normal, the patient was flushed, the temperature 106° F, the pulse-rate 36, and the respiration-rate 36 (The temperature remained above 101° F throughout the illness, except during the two hours following lumbar puncture)

During the day the patient was semi-conscious, with periods of delirium; obviously there was severe toxæmia Blood was taken for a Widal reaction, which was reported negative for the typhoid group

On the 29th the boy persisted in lying on his right side, with the head thrown back, his condition rather suggesting meningitis, although Kernig's and the usual ocular signs were absent Lumbar puncture was performed, and about 5 c cm of fluid were withdrawn, it was clear and not under pressure He seemed slightly relieved for a few hours, and the temperature, pulse- and respiration rate dropped, but they rose again later Blood and fluid were put into culture media, but on incubation proved sterile No clot formed in the fluid on standing During the day delirium became more marked, morphia gr 1/6 was of no avail, later hyoscine hydrobromide gr. 1/100 quietened him for some hours

---

[1] Chick and Roscoe. Biochem Journal, 1926, No 3, xx, 632–649

On the 30th he was delirious and required restraint; by about midday his pupils had dilated, the head was retracted, and breathing had become stertorous He collapsed suddenly about 3 P.M.

At the *post-mortem examination* made by Dr L Cunningham, pathologist to the hospital, nothing abnormal was found except a mass of enlarged hæmorrhagic glands in the left groin These were removed and submitted to Dr L S Ashcroft, assistant city bacteriologist, and bacteriologist to the hospital. Direct smears showed organisms very suggestive of *Bacillus pestis* A guinea-pig and rat were inoculated, and within 24 hours were obviously fatally affected, they died within 48 hours, and cultures from them confirmed the suspicion of *B pestis* infection.

CASE 2—The father of the boy, aged 60, came to the hospital on August 30th in connexion with the death of his son. He looked ill and on question complained of having had headache (pains over eyes and back of neck) and nausea since the previous Friday; he also felt "good for nothing" and looked it When asked, he said he had a small swelling in right groin, only noticed on Sunday, and not painful His temperature was 98 6° F and varied between that and 97° while in hospital The pulse-rate was 120, and settled down to 100, the respiration-rate was 28, and varied between 20 and 28 The bowels were rather constipated

With some persuasion he came into hospital for a rest; and on further persuasion he agreed to part with his gland; this was removed on the following day under local anæsthesia, and was found to contain pus This, with a portion of the gland tissue, was sent for bacteriological examination, results being again indicative of *B pestis*

The man and his family were taken to the Port Isolation Hospital, but no further cases developed

Four weeks later, after discharge from isolation, he looked much fitter and was ready for work

This patient (Case 2) worked in an office on the grain wharf. He was not employed in actual contact with cargo, but there were rats in his office, and one had been seen in his home. It is suggested that the train of infection was probably from a grain ship, via grain wharf and office to the man, and thus to his home. A thorough investigation and all necessary precautions were taken in hand by the public health authorities

I am indebted to Dr. J Murray Bligh, senior physician, and Dr L Cunningham, assistant physician, for permission to publish these cases, which were admitted to hospital under their care

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

COMBINED SECTIONS OF ODONTOLOGY AND DISEASES OF CHILDREN.

ON April 6th these Sections held a joint discussion on

ORAL MANIFESTATIONS OF GENERAL DISEASE IN CHILDREN,

the chair being occupied by Mr J B. PARFITT, the President of the Section of Odontology

Mr A T PITTS presented the point of view of the dental surgeon to whom, he said, nothing appertaining to the mouth was foreign He would not attempt to catalogue the oral manifestations which were due to systemic disease, but would pick out for consideration some which had come under his notice and excited his interest, and he would ask questions to which an answer would be valuable

Osteomyelitis of the maxilla might, he said, occur in babies only a few months old Was the condition in these infants a true osteomyelitis or an antral infection? As in very young subjects the maxilla was a thin shell of bone containing the developing teeth, the crypts of the teeth soon became infected. and often such cases came under the dental surgeon's care The treatment should be cautious and limited The necrosis might last a long time, but it did not seem to become acute nor to spread rapidly. In cases of tuberculosis of jaws which he had seen in children the infection had been in the mandible, and he asked whether in these cases the disease was secondary to tubercle in some other part of the body Could it occur in a clean mouth, or must there already be a dental infection?

Turning to localised suppuration of the jaws which originated elsewhere than in the teeth, he said that cases were sometimes encountered in which the conditions resembled alveolar abscess, and he asked for suggestions as to their pathology In order to exclude a dental cause a radiogram must be taken; apparent healthiness of the teeth was no criterion. He had seen a number of cases of this kind in which the patient had been for some time under medical care without the condition having been suspected Removal of the offending tooth had led to cure

Necrosis of jaw following scarlet fever appeared to have been common some time ago, but was now rare An instance had been reported to the Odontology Section by Mr T B Layton With regard to tooth changes found in congenital syphilis. Mr. Pitts said that Hutchinsonian teeth showed two features—namely (1) an alteration in the architecture of the tooth, so that its sides converged towards the cutting edge; (2) the existence of an area of badly formed enamel on the cutting edge; or there might be an actual deficiency of enamel leading to a notch or rendering one likely. Speaking of anomalies of eruption and development, he asked whether rickets retarded eruption and if so, whether the retardation only affected the deciduous teeth or also the permanent ones Sometimes dentition was in advance of the child's years Did this point to the development of the teeth being regulated by the endocrine glands?

In conclusion Mr Pitts dealt with oral manifestations such as scurvy due to vitamin deficiency It had been suggested, he said, that follicular stomatitis in children could be attributed to lack of water-soluble vitamin B

Dr. ROBERT HUTCHISON, from the medical aspect said that the affections of the jaw in general disease were more surgical than medical, but general hypoplasia of the skeleton—e g in some forms of infantilism—affected the jaws, and it was interesting to speculate as to what part was played in this by endocrine disturbances Over-action of the anterior lobe of the pituitary caused an overgrowth of the lower jaw in acromegaly. and possibly pituitary deficiency might result in under-development of the jaw during the period of growth But in cases of dyspituitarism such an under-development did not occur. There was even less reason to believe that deficiency of vitamin B in the diet could interfere with the development of the jaw as had been suggested. Rickets, however, could act in this way, though he thought it did so less than had been supposed.

The teeth seemed to be more affected by general disease than did the jaw. In rickets the appearance of the teeth was delayed He thought the teeth were a better index of the real age of the patient than was the stage of ossification of the epiphyses The influence of general disease on the calcification of the teeth was very important. as was well seen in rickets and Mrs Mellanby had shown that this was due to a deficiency in vitamin A. The effect of inherited syphilis on the teeth was well recognised, and anything which impaired the general health might interfere with the laying down of enamel; measles and pertussis were very apt to act in that way Dr Hutchison thought that variations in the reaction of the saliva due to affections of general health might affect the enamel In nervous children the saliva was apt to be unusually viscid Children who were mentally defective and those who suffered from dyspepsia—perhaps also those with worms—were apt to grind their teeth The gums, being highly vascular, easily became affected in hæmorrhagic diseases, such as scurvy, the lymphatic leukæmias, and purpura Hypertrophy of the tongue was met with in cretinism, and to some extent in Mongolism Affections of the mucous membrane of the mouth were, in his view, for the most part purely local, and did not indicate any general disorder This was certainly true of the common forms of stomatitis, but in the ulcerative and gangrenous form lowering of the general health played a large part He did not feel convinced, however, that vitamin deficiency was a factor in this debility In the delayed form of inherited syphilis there might be perforation of the soft palate; often it was associated with interstitial keratitis He could not say whether the teeth also were affected

Summarising, Dr Hutchison said that the oral manifestations of general disease in childhood were, except in the case of the teeth, neither numerous nor important He believed, also, that too much emphasis was laid on the supposed effects of oral disease on the general health.

Discussion.

The **PRESIDENT** said that the great resistance of the oral tissues to trauma and to all kinds of bacterial invasion might partly explain why the oral manifestations of disease were not very marked

For the production of caries it seemed necessary that certain organisms should be present, but there must be something in addition, otherwise every tooth would be carious He had met with ropy saliva in association with caries, but not in children, though they were particularly liable to caries He wondered whether there might be some endocrine disturbance which influenced the degree of immunity to bacterial invasion. And in periodontal disease there was some factor beyond mere infection, it was rare in children, common in adults The dental surgeon could keep a careful watch on the children who came to him from time to time, and if he found that a child who had been normal began to develop facial irregularity or caries, he should see that the medical man was apprised of it

Dr **H C CAMERON** spoke of two distinct types of children, in one of which the teeth were habitually faulty, whilst in the other they were comparatively well formed, well erupted, and with good enamel. Caries was apt to occur chiefly in the child with a high lymph content in its body, as shown in adenoids and enlarged tonsils Such a child had a large appetite, a clean tongue, and loose bowels, and showed a marked tendency to catarrh; this catarrh, he thought, conduced to an inefficient functioning of the enamel organ Sometimes in these children the molar teeth were not erupted vertically, but lay almost on their side, so that instead of the grinding surfaces meeting surface to surface they met at their edges The other type of child, with good teeth, usually had an intellectual inheritance, and the metabolic instability with which this was usually associated, often including attacks of sickness and cyclical vomiting. Mothers were frequently advised to see that their children were given hard foods so that vigorous biting was necessary, in order to ensure a proper development of the jaws But he thought a child who developed well and had good neuromuscular control, and who walked and talked early, could be trusted also to use its jaws efficiently. On the other hand, a child whose infancy was punctuated by repeated attacks of catarrh and who was slow in walking would probably use its jaws late and perhaps insufficiently

Dr **DAVID NABARRO** dealt with the question of the teeth in congenital syphilis He said that when people talked of Hutchinsonian teeth they had in mind the teeth which showed the characteristics grossly so that they could scarcely be missed Such teeth were rare The common Hutchinsonian teeth were those with the characteristics less marked, and they were often overlooked His experience was that the lower incisors showed these features when the upper incisors were markedly Hutchinsonian; they were small, their anterior surfaces were very convex, and the teeth were widely spaced. He had looked up the records of 208 children under 7 years of age Of these 32 had typical Hutchinsonian teeth, whilst the remainder had not He had had 12 cases of ulceration of the palate in 12 years This, with perhaps gummatous disease of bone, was evidence of syphilis Most of these children were from 8 to 10 years of age In only one of the 12 cases were the teeth Hutchinsonian, and in this case the boy had bosses on the head, was deaf, and had interstitial keratitis and choroiditis, yet he looked healthy, and it had been difficult to persuade the parents to let him come for treatment In two of the other children there was wide spacing between the lower incisors, and one had a notched incisor. Therefore it was not possible entirely to accept Hutchinson's statement that the teeth were not affected when the palate was ulcerated In cases of ulceration of the palate the Wassermann was very resistant, he had got a negative Wassermann in only four of the 12, and in the others it was resistant, though tested over a period of five or six years, the children meantime having had 20 to 40 injections of novarsenobenzol He had examined the cerebro-spinal fluid of 11 of the 12 patients, and in all but one of them it had been negative, that one case had had hydrocephalus and optic atrophy.

Mr **F. N. DOUBLEDAY** related a case in which the diagnosis of syphilis was made because of lesions of the mouth, and in which the conditions had turned out to be lichen planus with unusual oral manifestations Dr Hutchison, he thought, was apt to belittle manifestations of disease as found in the mouth. A condition in children which might somewhat simulate osteomyelitis of the jaw of adults was an infection of the crypts of the permanent teeth beneath the temporary teeth Stomatitis due to *Bacillus fusiformis* yielded readily to treatment with chromic acid He asked about the influence of preparations of ductless glands on some mouth conditions in children In the case of a woman, aged 18, who seemed like a child of 8. the medical man had given ½ gr doses of dried thyroid extract, after which she began to grow, and the teeth erupted well He had also seen cases in which the jaws grew after anterior pituitary extract He expressed his regret that so many practitioners advised mothers to give their children plenty of sweets, for he believed that such messes remained only partially digested in the alimentary tract and afforded a suitable pabulum for streptococci

Dr. **J KINGSTON BARTON** thought that much of the maldevelopment of the lower jaw seen in children and also in adults was due to bad feeding in early childhood He agreed with what Mr Doubleday had said in regard to children eating a lot of sweets

Mr **P. G DOYNE** spoke of the association of lamellar cataract with defective enamel on the teeth His experience was that Hutchinsonian teeth were infrequently associated with interstitial keratitis

Dr **A LIVINGSTON** said there were two types of inflammation of the gum margin—one of them local, due to carbohydrate stagnation, and the other caused by a general lowering of the resistance of the body, often accompanied by constipation or by such systemic upsets as diarrhœa

Dr **ALAN MONCRIEFF** asked whether the statement was true that in congenital syphilitics the teeth commenced to erupt much earlier than normal.

Mr **HAROLD CHAPMAN** said that he regarded irregular teeth as an expression of bad development of the maxilla and mandible, and therefore of the bones of the face He had no reason to believe, from the investigations he had made, that an undeveloped or a badly developed jaw was due to bad feeding The question whether orthodontic treatment should be accompanied by medical treatment was one for the decision of the general physician

Mr **PITTS** and Dr. **HUTCHISON** replied

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING of this Society was held at Liverpool on April 1st, Prof. FLETCHER SHAW, the President, in the chair.

Dr. J. W. A. HUNTER described his observations on

Experimental Endometrial Grafts

Although, he said, a considerable amount of work had been done on this subject, all workers appeared to be satisfied when they had demonstrated the possibility of heterotopic endometrial growth. No one had as yet reproduced in animals a condition comparable to that of tarry ovarian cysts in women.

His own work had been carried out on some 40 rabbits and the transplants were mostly autogenous, but a few were heterogeneous. The general reaction obtained was the growth of a multilocular cyst lined by columnar epithelium which was non-infiltrating; there was stromal proliferation in the papillary buds only. In rabbits killed on the third and tenth days after grafting two methods of cyst formation were found. The epithelium either dipped down into the graft to form a cyst, or it covered the graft and lined the under surface of the layer of fibrin which sealed in the graft. It was also noticeable in these experiments that whilst the columnar epithelium was scanty in the depths of the graft, it always covered the outer surface and grew along the lines of tissue junction. The stroma in the early stages was engorged.

In order to test the effect of vascularity some grafts were placed in the liver and some in an avascular part of the abdominal wall in the same rabbit. The former showed considerable proliferation of the endometrium with preservation of the racemose gland arrangement, but it was surrounded by a definite capsule. The latter showed a scanty growth of epithelium of a low activity. Even after 290 days a very active growth was found in the liver, but growth was not so exuberant in the ovary. In another animal after 388 days the general reaction was obvious, and after 760 days very small cystadenomata were found in atrophic ovaries.

To test the influence of ovarian hormone grafts were made into the ovaries; two ovaries from another animal, containing corpora lutea, were transplanted into the abdominal wall. Fifty-four days later very large cystadenomata were found with adhesions to many adjacent organs; microscopically they showed large thin-walled cysts without invasion of surrounding structures. This result could only be obtained when the grafted ovaries from another animal contained corpora lutea. In an experiment in which the grafts were placed in the abdominal cavity of a male rabbit it was found 30 days later that there was no trace of the columnar epithelium, but the gland spaces remained. An attempt to confirm the "serosal" theory by the implantation of pieces of peritoneum and subperitoneal tissue gave a negative result, although there was an active growth of the mesothelial tissues. In one case in which grafts were placed in the ovary, and the ovary was then transplanted into the abdominal wall, definite endometriosis with invasion was produced.

Dr. Hunter concluded from this series of observations that fragments of endometrium, when grafted into any organ, could grow. The factors which controlled growth of the stroma and endometrium were not the same, and the hormone of the corpus luteum had a selective action controlling growth of the endometrium, more especially its epithelial portion. The experiments showed, he said, that whereas implanted endometrium could continue to grow for an almost unlimited time it did not, under normal circumstances, become invasive. In the one instance in which an abnormal factor was present (transplantation of the ovary which was the site of the graft) the typical picture of endometriosis was obtained. This rather suggested that for the production of the human picture one factor—either the endometrium or the invaded tissue—must be abnormal.

Dr. Hunter expressed his indebtness to Prof. H. S. Raper and the staff of the Physiology Department of the Victoria University, Manchester, for the facilities extended to him.

Dr. S. B. HERD asked whether the time in the œstral cycle at which the endometrium was taken for grafting made any difference to its capacity for growth.

Prof. BLAIR BELL expressed his appreciation of Dr. Hunter's work. He passed round a specimen—one of several—obtained in his own laboratory, showing that it was possible experimentally to secure not only an endometrial tumour by implantation, but also, during pregnancy at any rate, to produce a shower of glandular implants over the whole peritoneal surface of the abdominal cavity.

The PRESIDENT also congratulated Dr. Hunter on his work, and stressed the importance of comparing clinical and experimental results.

Dr. HUNTER, in reply, said that in his experience the time in the œstral cycle at which material was obtained for grafting made no difference to its capacity for growth.

Prof. DANIEL DOUGAL reported

An Unusual Malformation of the Left Broad Ligament

A married nullipara, aged 45, complained of a blood-stained discharge of 12 months' duration; a severe hæmorrhage had occurred two months before she was seen. The uterus was enlarged; the cervix was much thickened, very hard and stretched, and there was a good deal of bleeding on examination.

On opening the abdomen it was found that the uterus contained a number of fibroids, including one in the cervical canal. The main interest, however, lay in the malformation of the left appendage. The left ovary lay with its inner pole close to the internal abdominal ring, and running from it into the inguinal canal was a thick muscular cord, about one-eighth of an inch of this being visible between the ovary and the ring. The ovary was normal in appearance. The left Fallopian tube was somewhat small, and terminated on the outer side of the ovary more than 2 inches from the uterus. The fimbriated end was fully developed. The kidney and ureter were completely absent on this side.

Running from the ovary towards the uterus was a fold of peritoneum, in the outer part of which could be made out a fibromuscular structure which tapered to a point and terminated about 1 inch from the uterus. The peritoneal fold joined the uterus about the junction of the body and cervix. The right ovary and tube were apparently normal, and were attached to the uterus at a much higher level than the peritoneal fold on the opposite side. The uterus itself was much distorted by the presence of fibroids, but was assumed to be of unicornuate type, the left horn being completely absent. The upper part of the left Müllerian duct formed the Fallopian tube, and there the further development of this structure had ceased. The Wolffian structures on this side were evidently absent.

The position of the ovary at the internal abdominal ring was interesting, said Prof. Dougal, as the fibromuscular cord attaching it to the ring presumably represented both ovarian and round ligaments. As the Müllerian duct on this side had not grown inwards to fuse with its fellow of the opposite side the gubernaculum had drawn the ovary straight downwards to the inguinal ring. The malformation was undoubtedly rare, and he had only been able to find a record of one somewhat similar case, published by Bonnaire and Durante in 1912.

Prof. BELL said that true uterus unicornis was very rare. Most cases so described had been, in reality, cases of uterus bicornis in which one horn is poorly developed. Two other points of interest were demonstrated in Prof. Dougal's specimen. First, the ovarian ligament on the side on which the uterine horn had not developed ran straight to the inguinal ring, indicating the truth of views emphasised by Prof. Bell many years ago that the round ligament and the ovarian ligament were one structure, and together represented the gubernaculum. The second point of interest was that, although the Fallopian tube as a whole was not formed, the fimbriated extremity was present—a matter of common observation in many cases of malformation of the parts, and one which bore out Keith's contention of the origin of the fimbriated extremity from the pronephros

Prof **Dougal** also described a case of

Unilateral Duplication of the Ureter with One Ectopic Opening

The patient, aged 24, unmarried, consulted him because of deficient control over micturition almost since birth She was able to pass urine in the ordinary way, but in addition was wet both night and day She always wore a diaper and used three in the 24 hours, one during the night and two during the day

On inspecting the vulva Prof Dougal thought that he observed urine welling up from the vagina He therefore decided that the condition was more than a mere weakness of the sphincteric control of the bladder, and admitted her shortly afterwards to a nursing home for further investigation under anæsthesia During this examination he found that the urine escaped periodically from a small opening in the vestibule just below the urethral opening and a little to the right of the middle line The urine coming from this opening did not pass through the bladder, and it was therefore evident that the condition was one of ectopic ureteral opening

It was suggested that a general surgeon be called in to investigate the urinary tract, and Mr Wilson Hey found that there were two ureteral openings normally situated in the bladder, and that both were acting normally In addition there was a second ureter on the right side and this one had an ectopic opening on the vestibule Sodium bromide was injected into the bladder opening of the right ureter, but only a small quantity could be passed in, and there appeared to be some obstruction in the upper part Sodium bromide was also injected into the ectopic opening of the right ureter and passed freely up to the renal pelvis

Evidently the patient had two pelves and two ureters on the right side, said Prof Dougal, and one of these ureters had an ectopic opening from the vestibule The abnormality was obviously of clinical importance, but was also interesting from an embryological point of view, as the ectopic ureteral opening in this case was situated at the point where Gartner's duct was usually supposed to terminate An exhaustive paper on the subject had been published by Kilbane in *Surgery, Gynecology, and Obstetrics*, 1926, vol xlii

Prof **Ernest Glynn** described a case of

Idiopathic Dilatation of the Bladder

The patient was a woman aged 48 Trabeculæ were well developed in the bladder and a small sacculus was present There was also a moderate amount of bilateral hydronephrosis The uterus was normal Prof Glynn had made post-mortems on two similar cases in men, and wondered how far such a condition might be produced by habit It must be remembered that idiopathic hypertrophy of the bladder with hydronephrosis was described in children He himself had seen the condition post mortem in males aged 12 and 16

Dr J E **Gemmell** described two cases he had seen In the first no cause could be assigned but in the second the condition had certainly been due to habit Finding it very difficult to leave her work, the patient had accustomed herself to going all day without emptying her bladder

Dr W W **King** also quoted two cases due to habit, one in a cinema pianist and the other in a chronic alcoholic who had prolonged periods of unconsciousness

Prof **Glynn**, in reply, quoted a similar case in a policeman who was on point duty for long hours at a time

Prof **Blair Bell** described a case of

Primary Adenocarcinoma of the Fallopian Tubes

The patient was a 1-para aged 45 She complained of pain in the back and hypogastrium and a yellow inoffensive discharge for 12 months, there was frequency of micturition and she became exhausted on the slightest exertion The uterus was thought to be enlarged, irregular, and immobile A large swelling was felt through the anterior fornix evidently pressing on the bladder A hard mass was felt on either side of the uterus Panhysterectomy with bilateral salpingo-oöphorectomy was performed, but was extremely difficult owing to the density of the adhesions and the presence of bilateral ovarian cysts, which appeared to burrow deeply in the loose tissues of the pelvis Subsequently a small vesico-vaginal fistula was found and easily repaired

Primary carcinoma of the Fallopian tube, said Prof Bell, was rare, less than 150 cases being reported in the literature Probably the condition occurred with greater frequency, but the cases were not recorded He had had three cases but the other two cases had not previously been fully reported In reply to a question, he said that he considered primary carcinoma of the Fallopian tube on a par as regards malignancy with adenocarcinoma of the body of the uterus For a long time, that is to say, the disease remained enclosed within the tube and during this period extension or metastases were rare Once however, the tube wall was penetrated extension was rapid

Prof Bell also showed three cases of Krukenberg tumour and a case of carcinoma of the cervix with pregnancy

Mrs **Dobbin Crawford** reported a case of double vaginal cyst arising from Gartner's duct

NORTH-WESTERN TUBERCULOSIS SOCIETY.

A meeting of this Society was held in Manchester on March 31st, Dr A **Adams**, the President, in the chair

Prof S **Lyle Cummins** read a paper on

The Bearing of Recent Laboratory Research on Clinical Conceptions in Tuberculosis

His experience in the post-mortem room, he said, had impressed upon him the pleomorphism of tuberculosis in human beings as compared with its uniformity in animals In the laboratory animal there existed what might be called natural tuberculosis, the same characteristics being found also in infants and primitive races—namely, generalisation of the disease with rapid termination This was in contrast with tuberculosis as usually seen in human beings—that is to say, pulmonary disease Some modifying factor appeared to have been at work, and modified tuberculosis tended to be localised in the lungs In between was the big zone of surgical tuberculosis It was the aftermath of an unrecognised general tuberculosis causing metastatic deposits via the blood stream A later stage was localisation of the disease in the lungs In natural tuberculosis the tuberculin test produced a negative or slight reaction, in modified tuberculosis it produced a marked reaction Natural tuberculosis was characteristic of non-allergic age-groups and races, whilst modified tuberculosis was characteristic of allergic age-groups and races, the modifying factor being the production of allergy

There were three questions concerning pulmonary tuberculosis which were still unsolved 1 Is the disease caused by the reawakening of an infection in childhood, or due to the reinfection of an allergic lung? 2 Do the bacilli enter through the alimentary tract or by the inspired air? 3 Why is the disease more commonly apical than otherwise?

As regards the first question, much experimental work had been done Baldwin had taken infected guinea-pigs and had tried to reinfect them, he had found them very resistant to reinfection but had succeeded with large doses Krause and Willis had introduced an emulsion of bacilli into the skin of guinea-pigs, and had found that, even one hour after inoculation, excision of the piece of skin infected was too late to prevent infection of the animal If, however, the animal had previously been infected, five days was not too late which showed that there was great retardation in infected animals Similarly, they had found that in previously uninfected animals the neighbouring glands were reached within 24 hours, but in animals previously infected they were not reached in 21 days Thus a previous infection caused retardation and modification of disease The presence of scars in the lungs of adults was evidence that much early tuberculosis in children did heal

There was a correlation between physiological influences—e g , childbirth, lactation and strain—and infection, and this pointed to the awakening of an old infection On the other hand, no infection came from healed scars It was difficult to establish definite sources of infection, but these certainly did occur Experiment had shown that if an emulsion of bacilli was injected into the posterior nares of rabbits under an anæsthetic either lung could be infected Soper had repeated these experiments with X ray control, and definite parenchymatous lesions had been shown in the lungs of allergic rabbits long before rabbits previously uninfected showed lesions But the reaction in the latter, though delayed, was more serious Calmette held such experiments to be unnatural The evidence on the first question was thus inconclusive, but it was clear that pulmonary tuberculosis was due to a reawakening of previous infection, and there was strong evidence in favour of reinfection

As regards the second question, continued Prof Cummins, Calmette believed in the alimentary route of entry Guinea-pigs fed on fatty broth containing bacilli showed bacilli in the lacteals in three hours In early life the mucous membrane was more easily permeable ; on the other hand, it was to be noted that in later life most bacilli in the lungs were of human type, whereas swallowed bacilli were usually bovine Moreover, in spite of much swallowed sputum, intestinal ulceration was comparatively rare Calmette, however, maintained that in animals infected in the laboratory the lungs were always infected. Prof Cummins himself believed that both types of infection occurred

Referring to the third question Prof Cummins quoted Bacmeister's experiments in which the apices of rabbits' lungs were constricted by rings When bacilli were injected intravenously (ear) there was a concentration of bacilli under the rings, but when bacilli were puffed down the respiratory passages no such concentration occurred, the lesions being general in the lungs These experiments could not really be regarded as satisfactory, owing to the stagnation of the circulation caused by the rings He had himself made observations on groups of coal-miners and had found that in those who had worked with silica the lymphatic blockage was more effective at the apices than elsewhere, whereas normally coal dust was readily dealt with by phagocytosis

A discussion followed

Reviews and Notices of Books.

THE SPECIALITIES IN GENERAL PRACTICE

Compiled by FRANCIS W PALFREY, M D , Instructor in Medicine at Harvard University in collaboration with others London and Philadelphia W B Saunders Company 1927 Pp 748 30s

THIS book has been skilfully designed " to simplify the problem of the general practitioner in dealing with specialties " Recognising that in the course of his training the medical student's instruction in special subjects is usually insufficient to give him practical familiarity with them, the compiler of the volume has produced a mass of information on these subjects which, while concise enough to stand as a reference book, is discursive enough to provide good reading There are 11 sections the first on dermatology written in collaboration with Dr Lawrence Oliver, introduces a new classification, in which symptomatology rather than pathology is the determining factor , this arrangement should be of assistance to the practitioner, as it is for symptoms that his patients present themselves, and the pathology of diseases of the skin is especially obscure This section occupies over 100 pages Dr Dellinger Barney has assisted in the succeeding section on genito-urinary surgery An essay on sexual hygiene is followed by concise descriptions of the common diseases met with in practice In the third section, on gynæcology, Dr W P Graves and Dr F A Pemberton collaborate with good results Dr Crosby Green helps with the fourth section which deals with rhinology and laryngology , special attention is paid to the various types of sinusitis Dr James Torbert is concerned with a 40-page section on obstetrics in which antenatal care and examination receive emphasis , an extended position of the thighs during the passage of the perineum in labour is thought to be prophylactic against perineal tears A systematic description of ophthalmological conditions constitutes the sixth section, the subject matter being founded on Harvard lectures by Dr George Derby The failure of the general practitioner to recognise early glaucoma is stressed

Some lectures by Dr R B Osgood and Dr N S Allison are the basis of a large section on orthopædics , in it methods of examination are usefully tabulated Arthritis deformans is divided into the atrophic or proliferating and hypertrophic or degenerative types, alternative names which do not flatter the ætiological knowledge of chronic arthritis now available Talipes, wry-neck, and other deformities are dealt with, foot-strain receiving special attention Dr Harold Walker's lectures on otology form the basis of the eighth section, which is prefaced by a good anatomical summary Diseases of infancy and childhood are well condensed in a section on pediatrics compiled with the help of Dr Richard Smith and Dr. Randolph Byers , it includes a useful page or two upon examination of the new-born infant and an efficient account of breast and artificial feeding, cows' milk being set forth as the proper basis for the latter The tenth section on psychiatry, written by Dr H C. Solomon, is an excellent instance of the useful nature of the whole book Probably in no specialty is the average general practitioner so little instructed as in mental disease, and this section provides in a simple form a detailed survey of abnormal psychical states whether dependent on gross disease or functional The volume ends with a section of 100 pages on surgery, which omits few common conditions from its concise survey, and deals briefly with such practical emergencies as shock, drowning, hæmorrhage, and snake-bite It is written in collaboration with Dr Channing Simmons, and concludes with a very complete schematic tabulation of the treatment of fractures

This book in all its eleven sections, draws attention in a valuable way to, and provides a remedy for, a very real need in the busy life of the general practitioner It steers a middle course between the rule of thumb method and too much discursiveness , the teaching is orthodox, definite and practical, and should ensure the success of the book All concerned in its production are professors or instructors in the Medical School of Harvard University

MEASLES

La Rougeole—Épidemiologie, Immunologie, Prophylaxie By ROBERT DEBRÉ and PIERRE JOANNON. Paris Masson et Cie 1926 Pp 288 Fr 35

A SURVEY of the recent work on measles from the standpoint of epidemiology, immunology, and prophylaxis is most opportune This work does not pretend to be an exhaustive treatise but contains largely the authors' own experience and research, and is a useful contribution to the literature of the subject of measles The first part of the book deals with epidemiology, and includes chapters on the mortality from measles and the factors influencing it, such as sex, age, surroundings, and the social factors concerned in the greater death-rate amongst the working classes In the second part, dealing with immunology, the authors discuss the susceptibility of man, the various types of the disease, infectivity, and the production of immunity. Lastly, there is a section on prophylaxis, which contains a chapter on general prophylactic measures The remainder of the section—which takes up about half the book—is devoted to an exhaustive account of the prevention of the disease by means of serum from a convalescent patient. Numerous protocols are described in detail A chapter is devoted to the obtaining and preservation of the serum, to its administration, and indications for its exhibition Full details are given of results, and the reasons for failure are enumerated An account of the organisation devised for the collection and distribution of convalescent serum in France and other countries is included The use of blood and serum from persons having had measles some time previously, and not in the category of convalescent, is discussed Lastly, the authors review the literature on active immunity against measles, beginning with a full account of the work of the Edinburgh physician, Francis Home, who in 1758 applied blood from a measles patient to a scarified surface of the arm, as in vaccination against small-pox The account of the work on the active immunisation against measles up to the present date shows that the results which have been published up to the present are surprisingly meagre

The authors have produced a book which should be read by all those interested in the subject of measles The use of convalescent serum is particularly complete, and rightly so, as the authors have made notable contributions to the literature Indeed, the phenomena of blanching of the measles rash after the intradermal injection of convalescent serum (corresponding to the Schultz-Charlton reaction in scarlet fever) is known as the Debre phenomenon after one of the authors of this treatise The book is simply written Numerous diagrams and tables of statistics are included The bibliography is fairly complete, especially with regard to the work of French observers This work should appeal to those engaged in public health work and administration

---

TROPICAL SURGERY AND SURGICAL PATHOLOGY.

By K K CHATTERJI, F.R C S I, Major I T F Medical Corps London John Bale, Sons and Danielsson, Ltd 1927 Pp 244 16*s*

IN many respects surgery in the tropics does not differ materially in methods or execution from the art as practised elsewhere Tropical surgery, covered by this book, is a much more limited field, and the fact that "Surgical Pathology" has been chosen for the subtitle indicates that due attention is given to the life-history of those parasites to which tropical surgery, *sensu stricto*, is due Major Chatterji's book deals mainly with surgical conditions produced by two important parasites—the *Entamœba histolytica* and the *Filaria bancrofti*—and he has dealt with both in an able manner His descriptions of operative procedure and his knowledge of the underlying pathological conditions have been culled from quite an exceptional first-hand experience Hepatic amœbiasis, as experienced in India, is a much more complex subject than a superficial acquaintance of liver abscess as met with in Europe would indicate, while under filariasis quite a number of conditions are described which have remained unrecognised by the writers of text-books of tropical medicine Other sections worthy of comment are those on the tropical granulomata and the surgical effects of snake-bite, while the instructions for the preparation of saline injections for cholera and the methods of administration are clear and precise A number of statistical appendices and a useful bibliography are included This book contains many original ideas and methods, the author's apparatus, the simultaneous aspiration and irrigation of obstinate hepatic abscess, and his methods of injecting the ethyl esters of margosic acid in filarial hydroceles and cysts are noteworthy. Copious illustrations are given, to the Western eye the coloured plates are lurid and terrifying, but they are all original and clear A few curious slips might be amended in future editions The statement (p 39) that the phrenic nerve arises from the brachial plexus is inappropriate in a surgical work, nor do microfilariæ become "chitinised" in the hydrocele wall.

This is a book which should be read by every operating surgeon in the tropics, it must be considered as a solid contribution to Indian surgery.

NERVOUS AND MENTAL DISORDERS FROM BIRTH THROUGH ADOLESCENCE

By B SACHS, M.D, Consulting Neurologist to the Mount Sinai and Montefiore Hospitals, New York, and LOUIS HAUSMAN, M.D, Instructor in Neuro-anatomy, Cornell University Medical College London Humphrey Milford, Oxford University Press 1926 With 110 illustrations and three plates Pp 861 50*s*

THIS elaborate text-book on the nervous and mental diseases to which children and young people are subject has grown out of that older treatise, on the same topic, which was written by the senior author of the present volume when neurological conceptions were considerably different from what they are to day "New" diseases have made their appearance, and principles of approach to neurological problems are now oriented more from a physiological than from a morphological aspect Verbal descriptions of disease symptoms do not suffice, questions of pathogenesis and of ætiology have assumed greater importance, and we hear more of reactions to injurious agents or of biological responses to extrinsic or intrinsic stimuli than formerly In respect of so-called functional disorders the growing-point of neurology has altered materially in the course of the last 20 years Changes of these kinds are reflected in the volume under review, yet the essentials of careful clinical observation must always remain The chapters on encephalitis, poliomyelitis, extrapyramidal disease, endocrine disorders, may be selected as representing the embodiment of recent acquisitions to knowledge, and as conveying to the reader in a discriminating way such data as have been proved to have abiding significance Special interest attaches to the fifth part of the book, which deals in a sane and critical fashion with modern ideas in respect of the neuroses and psychoneuroses, as well as the psychoses, and contains a chapter on the normal child that is certainly not out of place in a text-book of disease, but is, on the contrary, as desirable as a section on neurophysiology.

Good bibliographies at the end of each section, and good illustrations, contribute to the excellence of this latest volume on neurological pediatrics

---

MENTAL GROWTH AND DECLINE

By H L HOLLINGWORTH, Ph D, Professor of Psychology in Barnard College, Columbia University. London and New York. Appleton and Co 1927 Pp. 396 10*s*

Dr Hollingworth writes for the general student and handles his subject practically. An example of his methods is the statistical testing of the belief that the only child is prone to emotional instability, and he shows that among college students at least there is no appreciable difference telling against the only child But he overlooks an inconsistency in his statistics when on page 30 he says that the degree of intelligence exercises a determining influence on the nature of neurotic complaints. He quotes Tendler's figures in support of this thesis, and on the next page gives his own figures which, on examination, show an influence in the opposite direction Matthew's questionnaire is a useful guide to the elucidation of emotional instability in children, though to classify results on the bare *yes* or *no* answers to written questions invites neglect of personal observation Indeed, spurious simplification rather mars the book.

Unconscious processes are ignored by the author, and even if this is done for the sake of his readers there is little excuse for the omission of essential details from the account of Rivers's case of claustrophobia; no mention is made of the forgetting of the early experience so fully described by Dr Hollingworth, or the revival of the memory and the disappearance of the phobia

The jacket inscription says, "Never before has such a survey of the origin, course, and destiny of human life been undertaken in a single volume and in terms of established psychological knowledge" The book certainly does give an account of human behaviour from the intra-uterine life of the individual to the development of social institutions, with explanation and comment that are not beyond the scope of the general reader

---

NEUROSYPHILIS.

La Syphilis Nerveuse By A. SÉZARY, Physician to the Hôpital Broca Paris: Masson et Cie. 1927. Pp. 208 3s 4d

WITHOUT pretending to cover the whole ground, Dr Sézary has written a series of what may be called essays in neurosyphilis, distinguished by the value of their subject matter as well as by a logical presentment and an easy and readable style Among these we have found the one devoted to the pathogenesis of parenchymatous neurosyphilis particularly useful, the arguments for and against the hypothesis of a neurotropic virus are marshalled and in turn discussed, and a definite conclusion unfavourable to the theory reached An essay on diffuse multilocular syphilis disposes of the view that there is more than a superficial resemblance between it and disseminated sclerosis We think Dr Sézary sound in his contention that the meningeal reactions accompanying parenchymatous neurosyphilis are effects rather than causes The chapters dealing with prophylaxis and treatment are equally enlightening and informative

On the whole, this is an excellent contribution to a subject of constant interest, and one to which we take pleasure in directing the attention of the *neurologist* and syphilologist

---

NOUVEAU TRAITÉ DE MÉDECINE

Publié sous la direction de MM les Prof G-H ROGER, F WIDAL, et P-J TEISSIER Fascicule IX, *Affections du Sang et des Organes Hæmatopoiétiques* Paris Masson et Cie 1927 Pp 802 F 80

THIS represents one of the most important additions to standard works on hæmatology made in any language in recent years The general conception is admirable, and its execution has been placed in the hands of men all of whom have in various ways been responsible for advance in our knowledge of the blood and its diseases The edifice of the volume is firmly based upon the rock of morbid anatomy; the sections dealing with therapeutics have obviously been edited with judgment and discrimination The references show that the authors of every section have brought their material fully up to date, and have, moreover, taken ample cognisance of work done in other countries It is true that the crow of the Gallic cock is heard occasionally, as when M le docteur Aubertin attributes the advance in the knowledge of pernicious anæmia since the time of Ehrlich to "l'impulsion de l'école francaise," but it is not unduly strident

English and American authors are chidden for their confusion of splenic anæmia of the Banti type with splenic hæmolytic anæmia Dr Aubertin and Dr Léon themselves lapse in their omission of the familial type of splenic hæmolytic anæmia from their classification Apart from this omission the section is admirable On the other hand, the section on the lymphadenomatoses contributed by Dr Clerc must be termed unsatisfactory It is true that lymphadenoma and the lymphatic affections in general offer one of the most involved and obscure problems in medicine, but to attempt to consider such fundamentally diverse conditions as lymphadenoma of the Hodgkin type, multiple myelomatosis of the Kahler type, chloroma, myeloid sarcoma, and mycosis fungoides all under the same head can only lead to even worse confusion The section on the purpuras contributed by Dr Pagniez and Dr le Sourd is one of the best in the book It provides the first serious effort we have seen to bring together all the recently won knowledge on the nature and functions of the blood-platelets and their rôle in purpuric conditions The section on chlorosis by Dr Aubertin and Dr Mouquin, though containing no new matter, is a masterly presentation of the subject Altogether an admirable work

---

AN INTRODUCTION TO THE THEORY OF STATISTICS

Eighth edition, revised By G UDNEY YULE London Charles Griffin and Co 1927. Pp 420 12s 6d

THIS text-book is so well known, and its merits have been so widely recognised by the attainment of an eighth edition, that our duty is discharged by commending it to all who want to acquire a working knowledge of statistical methods And this is an increasing number in the medical profession, seeing how much to-day not only the figures of population and of disease incidence but those of pathological findings and of therapeutic results are relied upon for the formation of definite conclusions The misuse of such figures is rampant among laymen, and many of our own profession are betrayed into statements about averages and means which persuade them to make general deductions, where even a superficial acquaintance with the theory of statistics would make them wary. In defence of medical men, it should be pointed out that statistics, as far as they concern the medical profession, form a particularly perilous weapon of argument For the quantitative data must always be affected by a multiplicity of causes The enthusiastic employers of statistical methods, when their significance has not been appreciated, are responsible to-day for a great many loose beliefs among the public, who rely unguardedly upon bold declarations having medical authority behind them but based upon no scientific familiarity with the employment of figures

---

A SYNOPSIS OF HYGIENE

Second edition By W WILSON JAMESON, M.A, M D, Lecturer on Public Health, Guy's Hospital, M O H, Hornsey, and F. T MARCHANT, Senior Assistant, Department of Hygiene, University College London J and A Churchill. 1927 Pp 514 18s

THE first edition of this book appeared six years ago, the work has now been brought so well up to date that it is practically a new text-book It covers in 11 chapters the subjects of meteorology, water-supplies, removal and treatment of waste matters, ventilation, heating and lighting, housing, food, personal hygiene (including matters pertaining to maternity and child welfare), epidemiology, vital statistics, sanitary law, and chemistry and physics Two appendices contain much useful information We have failed to detect any serious errors or omissions. In a future edition some discussion on the importance of disinfection might be added to the description of various methods of disinfecting, and the desirability of spacing beds in dormitories or barracks in order to prevent the spread of cerebro-spinal fever should be stressed The last entry in the table of factors on page 491 requires to be corrected Throughout the book the reader is referred to recent articles either in current medical literature or in Government publications dealing with the aspect of public health under consideration, and is thus made to connect his text-book knowledge with current practice Altogether an excellent book which can be highly recommended to teachers and students of public health

Quantitative Analysis

By J Barker Smith, L.R.C.P. London Imperial Press Pp 16 1s.

In this small monograph the author provides simple and rapid methods for estimating various constituents in foods, alcoholic beverages, silk, coal, urine, and other substances Evidently an enthusiast, he has removed the difficulties inherent in such work by ignoring them entirely, with the result that those for whom the pamphlet is intended would in many cases be unable to distinguish the reliable methods from those which are of doubtful accuracy To the qualified analyst the work offers several suggestions, which with further development are likely to prove of value, and those interested in quaint expression will fully appreciate the text

JOURNALS

Journal of Pathology and Bacteriology Vol XXX, No 2 Pp 185–512 April, 1927 —Experimental Pneumococcal Septicæmia and Antipneumococcal Immunity, by H D Wright (London) —Observations on Trypanosomiasis of Rabbits and its Natural Mode of Transmission, by H A Channon and H D Wright (London) *Trypanosoma nabiasi* is common in wild and rare in hutch rabbits, it produces no ill-effects, the animals cure themselves of the infection and are thereafter immune Infection can be propagated by infected blood, but without any great certainty, rabbit fleas work more precisely and appropriate experiments lead the authors to conclude that rabbits get the disease naturally by eating infected fleas —Variant Colonies of *Staphylococcus aureus*, by J W Bigger, C R Boland, and R A Q O'Meara (Dublin) The colonies are by no means always typical, many are white instead of yellow and may also be abnormal in consistence and colony-shape The variations are to some extent inherited —A New Method of Preparing Staphylococcal Hæmolysin, by the same authors Very active preparations are obtained by emulsifying agar growths in saline and centrifuging —On the Pseudohæmolytic Streptococci isolated from the Sputum in Pulmonary Tuberculosis, by W M Cumming (Glenlomond) Sputum generally contains streptococci which are hæmolytic on primary blood-agar plates, some of these are genuine hæmolytic strains, but in the majority the broth cultures will not dissolve red corpuscles; serologically this *S pseudohæmolyticus* is quite distinct from the recognised forms, though it is not homogeneous —Phenol and Tricresol Effects in Toxin-Antitoxin Solutions, by C G Pope (Beckenham) In a very interesting study of the effects of temperature on the mutual solubilities of water phenol and serum proteins it is shown that freezing may lead to such a separation of strong phenol as will destroy the properties of proteids and, as antitoxin is destroyed more readily than toxin, lead to Schick mixtures becoming poisonous —Benign Polyp of the Œsophagus of Great Size, by S C Dyke (Wolverhampton) A monstrous mass extending from the level of the cricoid into the stomach —Some Uncommon Tumours, by C Powell White and C E Brunton (Manchester). Sixty-four micro-photographs from 26 cases of tumours which are rare or remarkable in one way or another —The Effect of Heat on the Agglutination of Bacterial Emulsions, by A. N Goyle (London) Technical discussion of the effect of heat on the different agglutinable substances in typhoid and Gaertner bacilli —The Value of Different Kinds of Antigen in Prophylactic Enteric Vaccines, by J A Arkwright (London); we comment on this paper elsewhere (p 883) —The Effect of Ultra-violet Rays on the Rous Chicken Sarcoma, by C F. W Illingworth and G L Alexander (Glasgow) The filtrable agent which causes the sarcoma survives a longer exposure to ultra-violet light than common bacteria. The radiation of filtrates does not differentiate between the "virus" and the "specific factor" of Gye —Periodic Examinations of the Streptococci of the Human Throat, by the late C Ilis Fox and D. M. Stone (London). Any one throat maintains its dominant type of streptococcus over long periods; catarrhs are associated with the appearance or increase of hæmolytic forms —The Influence of Cultural Conditions on the Production of Diphtheria Toxin, by A F. Watson and E Langstaff (Beckenham). Those who make diphtheria toxin for the preparation of antitoxin on a large scale often have great difficulty in ensuring a satisfactory product It is shown here that the materials from which the culture medium is made, its heating in sterilisation, and the access of air during growth are important factors, but others evidently exist and are at present beyond constant control.—Observations on Lamb Dysentery, by T Hare and E E. Glynn (Liverpool) This disease often kills a quarter of the lambs in the north of England and south of Scotland in the first five days of life Its occurrence is very puzzling and cannot be closely related to anything in the mother Crowding increases its prevalence The authors suggest that it is essentially akin to melæna neonatorum with perhaps a secondary bacterial infection —The Use of Wild Rabbit Serum in the Laboratory, by W M Cumming (Glenlomond) Better than that of tame rabbits —Scrotal Cancer in a Tamil employed on Antimalarial Oiling, by A. N Kingsbury (Singapore) A fresh example of oil cancer —*The action of Bacillus typhosus* on Milk, by C Gorini (Milan) With specially stimulative media milk is first peptonised and afterwards clotted

Reports and Analytical Records.

COW AND GATE MILK FOOD

(West Surrey Central Dairy Co, Ltd)

In our issue of Feb. 19th last we published an analysis of this food obtained by the employment of the Rose-Gottlieb method, this gave the fat content at a lower figure than was claimed by the West Surrey Central Dairy Company, and as it now appears rightly claimed. The company having pointed out that the well-known method used in our analysis could only be expected to give satisfactory results with liquid milks, the further analyses, whose results are set out below, were put in hand, the Werner-Schmidt method being now employed It will be seen by the figures in the new analyses that the statements of the manufacturers with regard to the fat content in Cow and Gate Milk Food are justified The following are the results of two analyses —

	No 1 Per cent	No 2 Per cent
Moisture	2 94	2 83
Ash	5 98	5 93
Fat	26 62	27 20
Proteids	27 85	26 46
Lactose	36 40	37 05
Total	99 79	99 47

The analyses indicate that the samples of dried milk examined have been prepared from full cream milk of good quality with no addition

We regret that in the previous report a product, which we have on former occasions commended to the favourable notice of our readers, should have been misjudged

The Tuberculosis Society —The annual meeting of this society was held on April 8th at Somerville College, Oxford The following were elected officers for the ensuing year President Sir StClair Thomson, Chairman of Council Dr Roodhouse Gloyne, Council Dr Gloyne, Dr G T Hebert, Dr H Gordon Smith, Dr A Neville Cox, Dr C J Faill, Dr H A Ellis, Dr F R Walters, Dr A Sandison, Dr E Ward, Dr G M Mayberry, Dr G B Price, and Dr Jane Walker, Hon Secretary Dr F J C Blackmore, Hon Treasurer Dr W Brand.

THE LANCET.

LONDON: SATURDAY, APRIL 23 1927.

DOCTORS AND LEASEHOLD REFORM

While the Government, Landlord and Tenant Bill was being given a second reading, two speakers commented on its mission to give protection or relief to the professional classes and in particular to the medical profession The first of the three parts into which the Bill is divided proposes to allow a tenant compensation both for any improvements he has made and for any goodwill which he or his predecessors in title have built up at the premises in carrying on a trade or business But this part of the Bill applies only to leasehold premises used wholly or partly for carrying on a trade or business, premises where a profession is carried on are expressly excluded Criticising this exclusion, Mr **Hugh Dalton** observed that there are many doctors, dentists, and other professional men who are just as liable as anyone else to suffer from a landlord's confiscation of their improvements or of the goodwill with which they have endowed the premises during their tenancy. He instanced particularly the doctors in the poorer parts of London who have built up practices and, when their leases come to an end, must either pay a grossly excessive rent or be turned into the street This complaint perhaps requires remedy rather hrough the Rent Restriction Acts than through he Landlord and Tenant Bill, but it is serious Dr **Graham Little** spoke of the consultants argely inhabiting a particular district of London, who should be given the benefit of the Bill, and also f the general practitioners who in some cases have een obliged to build on leasehold premises in order to comply with the National Health Insurance Act equirements in the matter of waiting-room accommodation and so on Mr A **Maclaren** said that rofessional goodwill was assessable in the case of robate duty or when a practice passed from one octor to another There is a good deal of subtance in his contention that a man may knock at a oor in Harley-street with some confidence that the ractitioners inside have a particular reputation Professional men have endowed the Harley-street eighbourhood with its special rental value, a fact which the Bill does not sufficiently recognise Replying at the close of the debate, the Solicitor-General expressed sympathy and hinted that the Bill could be amended in Committee Two years ago the Finance Act extended to the professions the income tax concession in respect of the wear and tear of plant and machinery which had previously been granted to trades and businesses A similar extension is required in the Landlord and Tenant Bill In the second part of the Bill, which contains general amendments of the law of landlord and tenant, there is no discrimination against the professional classes The chief proposal here is that which prevents the landlord from unreasonably withholding consent if a tenant wants to assign or sublet the premises The law courts already have favoured the tenant in the interpretation of covenants upon this point, Parliament proposes to go further

Our ancestors would be surprised to see the extent to which the Rent Restriction Acts and the present proposals interfere with the contractual relationship of landlord and tenant They might equally be surprised at the high rents now charged to professional men, at the herding of several consultants in a single house like the congregating of barristers upon a stair-case in the Inns of Court, and at the system by which the lessee of a house, by subletting rooms to other doctors, can sometimes manage to live rent free—a system which cannot but suggest to the lessor that he might fairly raise the rent of the house a little higher It is an open secret that those who prepared and approved the Government's Bill found it difficult to interfere with the law of leaseholds without initiating a disturbance of the rights of ownership which might have had far-reaching consequences They therefore proceeded with great caution One feature of the Bill, the handing over of disputes to referees appointed by Reference Committees, has been criticised as multiplying the occasions for litigation It is also criticised by the legal profession itself, which does not particularly love the creation of new tribunals which grew up towards the end of the war But the county courts which otherwise would furnish the proper forum for the decision of landlord and tenant questions are swamped by the flood of cases which the Workmen's Compensation Act, the Rent Restrictions Act, and other statutes let loose upon them It is possible that the new tribunals will be efficient, but a tenant may well find that what he saves from the clutches of his landlord he will surrender to the clutches of the lawyers

◆

TYPES OF RESPIRATION

We publish in this issue the third and last of the Lumleian lectures on the Muscular Mechanism of Respiration and its Disorders by Sir **Charlton Briscoe**, whose previous work on disorders of the thorax and its contents is sufficient to ensure him a respectful hearing The subject is one on which anatomists and physiologists have already spent much time and labour, but the Lumleian lecturer shows us that there remain problems for investigation which, although they may at first sight seem of small importance, are yet nearly as weighty as they are difficult The muscular mechanism of forcible respiration is pretty well understood and the numerous muscles which may take part in it—they include in fact a majority of all those of the body—have had their rôles assigned to them as muscles of inspiration or of expiration; but Sir **Charlton Briscoe** deals with more elusive phenomena and confines his attention to quiet respiration His prolonged and patient investigation of the action of the diaphragm led him to inquire into the mechanism of respiratory movements and of pain and dyspnœa arising in respiratory muscles Two types of respiration have long been recognised, the thoracic and the abdominal—or as the lecturer prefers to call it, the diaphragmatic, from the preponderant action of that great muscular mass in the latter type After eliminating as far as possible the confusing influences of those muscles which are concerned in maintaining the posture of the body as well as taking part in respiration, it was possible to study the details of the process clinically in man as well as experimentally on the lower animals—this latter research being undertaken by Lady Briscoe. It is interesting to find that Sir Charlton Briscoe rejects the long accepted view that the abdominal muscles are of great importance in respiration owing to their supposed action in pushing up the diaphragm during expiration, although he acknowledges their help in thoracic respiration. In quadrupeds the diaphragm is almost the only muscle active in quiet breathing, and although the conditions are different in man, in him also this muscle is credited with doing most of the work, aided, however, by the active contraction or postural tonus of others. Sir Charlton Briscoe holds the view, however, that if exaggerated, these actions "are not a normal use of muscle but an abnormal over-use, and in consequence a possible source of trouble." The muscles of thoracic and those of diaphragmatic respiration may even in certain circumstances be antagonistic and so hinder each other's action. Various causes, which are specified, may result in enhanced and persistent tonus in certain muscles, notably the scalenus anticus and that obscure and often ignored structure, the triangularis sterni. The lecturer considers that the long maintenance of postural tone leads to pain and tenderness owing, as he thinks, to the fact that, in the absence of alternate contractions and relaxations of muscle-fibres, the contents of the veins are not duly squeezed out nor the arterial supply facilitated. In the musculature of the lower limbs and the vertebral column no such symptoms are observed to follow the prolonged maintenance of postural tone in everyday life, and more information would be welcome as to the conditions necessary for their appearance in the muscles concerned in thoracic respiration.

If the hypothesis be accepted that the diaphragmatic type of respiration is normal in orthograde man as well as in pronograde quadrupeds, and that the thoracic type is abnormal and out of harmony with man's evolution, it is easy to understand that such an improper use of muscles might give rise to pain and symptoms. It may be asked, however, whether, in assuming the erect position, man has not so radically altered the conditions of respiration as to render doubtful the aptness of an analogy between him and his four-footed ancestors—if indeed his descent is to be traced through quadrupedal and not quadrumanous forbears. As Sir Charlton Briscoe has pointed out, the assumption of the erect position relieved the thorax of the duty of transmitting the weight of the head and forepart of the body through the forelimbs, and so gave the thoracic muscles much greater freedom to act in respiration. In conditions so profoundly altered it would surely not be unnatural for a change in the type of respiration to occur without the production of unpleasant symptoms. The lecturer does not advocate a return to a pronograde posture and four-footed progression, although he thinks that it may be useful as an exercise for children, just as a well-known German surgeon advocated and employed his "crawling" method in the treatment of scoliosis. But if we accept it as established that in certain cases the habit of thoracic respiration throws overworked muscles into tonic spasm, it may be conceded that such a fixation of the thorax, even if incomplete, may hinder the action of the diaphragm and at the same time become obnoxious to the patient through the sensation of pain either direct or referred. Sir Charlton Briscoe has found that by pushing the lower ribs towards the pelvis such symptoms may be relieved, and that re-education of the diaphragm is possible, with the help if necessary of mechanical means, such as strapping the lower chest, or better still, constriction with a narrow webbing belt. By one or both of these procedures he has succeeded in relieving symptoms arising in quite a variety of disorders. Among these were cases of neurasthenia, disorderly action of the heart, tachycardia, gastric pain, the pain of pleurisy and of pleuritic adhesions, obscure chest pain on exertion, dyspnœa, persistent basal bronchitis, chronic influenzal bronchitis, nocturnal retrosternal pain and anxiety, and even asthma. The nature of some of these complaints, and their diversity or identity of symptoms, must arouse reflections as to the importance of suggestion in the relief of pain of obscure origin, but whatever part it may have had in the cases reported by Sir Charlton Briscoe, the fact remains, and is to be reckoned with, that a number of sufferers have been relieved of more or less distressing symptoms. We hope that other clinicians will follow the teaching and in appropriate cases try the effect of the method of treatment which he has described.

◆

OPHTHALMIC BENEFIT.

A Departmental Committee is sitting to consider the Optical Practitioners (Registration) Bill which has been read in the House of Commons for the first time and to make recommendations. This Committee will benefit by the wide range of experience possessed by its medical members, Dr. H. B. Brackenbury, Mr. E. Treacher Collins, and Dr. C. O. Hawthorne. The correspondence on this subject which has been appearing in these columns for many weeks past displays well enough the conflicting views of prescribing opticians and ophthalmic surgeons. The prescribing optician claims to be better qualified for the work of testing the refraction than the average medical man and as well qualified for it as the average ophthalmic surgeon. To ensure this high standard they propose that a register of opticians should be established which should include only those possessing special qualifications which in the future are only to be granted to those who have undergone a technical training lasting three years, and including experience at special "refraction" hospitals. At present the fee for testing allowed by those approved societies that send their members to opticians is 5s. and as presumably these highly trained "optometrists" will be content with this fee, it follows that the approved societies, and through them their members, will reap the benefit of the difference between 5s. and 21s. under which latter fee the ophthalmic surgeon is not willing to do this work. The opticians further maintain that the number of medical men qualified to do this particular work is insufficient for the demand which will be made if the work is given to them alone. They also point out that in the past the bulk of this work has, as a matter of fact, been done by opticians, and they regard the ophthalmic surgeon, inasmuch as he claims to do refractions for everyone, as something of an interloper.

The ophthalmic surgeon's case may be put shortly thus. The average general practitioner does not undertake this work. The ophthalmic "panel" consists only of such as have had special experience in eye work and includes a large number of those who practise ophthalmic surgery exclusively (Mr ADRIAN CADDY in his letter says "practically all," but we believe this to be an exaggeration) There is no evidence to support the contention of the opticians that the number is insufficient and there is every reason to suppose that the supply will increase with the demand The prescribing of spectacles cannot be done with complete satisfaction except by those who have a knowledge of the body as a whole—i e by medical men and women. The advisability or otherwise of wearing glasses is in certain cases a matter which requires considerable judgment and cannot be decided solely by reference to the amount of refractive error Moreover it is not a matter which can safely be left to the decision of those whose interest it is to push the sale of glasses by every possible means Diseases of the eye are frequently dependent on diseases affecting the whole body. The claim made by opticians that they are as well able to diagnose a normal fundus by the ophthalmoscope as the ophthalmic surgeon can hardly apply to the great majority of opticians at present Those who go through the three years' course and obtain admission to the proposed opticians' register will form a limited body of men who, while nominally only concerned in the prescription and supply of glasses, are not very likely to be content with that. As they will necessarily have to diagnose many cases of disease and abnormality other than refractive errors, the tendency will be for them to occupy the position of an inferior and partially trained body of oculists

Hardly enough attention seems to have been paid to the point of view of the insured patient For him the question is whether, when his eye troubles him, he would rather see a man capable of diagnosing and treating any possible cause of the trouble or a man who is admittedly capable of dealing with only one of the possible causes He will not, we think, be much troubled by the propaganda on cigarette cards which will enable the "mere child" to arbitrate between doctor and optician[1] Undoubtedly what the patient wants is to see the best possible man, even if this means a rather larger fee to be paid by his society. Possibly the solution might be found in the direction of an option given to the patient himself, in order to get the best possible advice he might be willing to pay the extra fee involved in a consultation with an ophthalmic surgeon out of his own pocket when his society declines to do this for him In any case it is essential that the privilege of choice of oculist from among the existing panel be more effectively brought to his notice than is the case at present with many of those societies that have already adopted the scheme of the Ministry of Health with regard to ophthalmic benefit This is the more necessary in that whereas opticians can and do advertise, ophthalmic surgeons do not Mr ADRIAN CADDY suggests that the list of names on the ophthalmic panel should be available to the public in the post offices Certainly all practitioners on the ordinary panel ought to have it If at the same time the body which controls the names to be included in the ophthalmic panel could be made more authoritative the whole matter would be in the way of reaching a satisfactory basis

Annotations.

"Ne quid nimis"

GLASS FRAGMENTS IN PRESERVED FOOD

WHETHER food is better preserved in metal or glass containers has not been finally decided, there is much to be said on both sides Glass has steadily been growing in public esteem on account of its cleanliness and honest transparency, but metal containers facilitate sterilisation and are more easily rendered air-tight Dr. Gerald Leighton a medical officer of the Scottish Board of Health, went carefully into the matter a few years ago[1] Glass has now its advocate at the British Ministry It is not uncommon to see in the press accounts of the discovery of particles of glass in foods and beverages sold in glass containers, and sometimes the paper adds a comment on the dangers of this method of packing Now and then an action is brought against a firm of provision merchants for injury caused by glass fragments that have become mixed with the food Glass containers are so widely used to-day that any danger that may exist must threaten great numbers of people and the Ministry of Health have rightly ordered an inquiry into the matter. The report[2] of the investigating officer will amply reassure those who have been anxious lest their jam lunch tongue, or bottled beer should contain a sufficient quantity of glass to do them any harm Evidence in this country of injury from swallowing glass is extraordinarily rare, the four largest London hospitals denied having seen a case in five years. Moreover, powdered glass seems to be less noxious than is popularly supposed It has enjoyed great notoriety in tales of Eastern life as a slow poison, but according to all the testimony quoted in Dr Hancock's report it is readily enveloped by the food in which it is concealed and by the secretions of the stomach and intestine Sharp-edged and angular fragments of appreciable size may cause damage, but these are hardly ever present The largest particles are found in jam—3/8 in × 5/16 in. was the biggest—but although microscopic glass is present in most samples it is much too small and scanty to do any harm Strangely enough, the actual container is the least considerable source of glass particles It is generally made of very good material, and Dr Hancock's analysts were rarely able to trace any of the glass they found to the jar or bottle in which they found it Semi-automatic processes produce safer vessels than hand processes The commonest ways in which glass gets from the container into the food are the use of returned empties, some of which have jagged rims, the neglect of proper inspection during washing and filling; and the failure to observe precautions when containers are suddenly subjected to a high temperature, as when boiling jam is poured into them There is considerable risk of glass contamination in sweet (and therefore sticky) mineral water, for the breakages are 1 or 2 per cent and fragments are liable to stick to the rubber pad which surrounds the orifice of the rotary filler Unless these are wiped off they may get into the next bottle Bottles are generally "sighted" for glass before they are passed for sale The commonest source of glass particles is the dust of the factory which contains not only glass but vitreous slag The report is illustrated with some interesting microphotographs of samples prepared by Dr F Monier-Williams, of the Ministry of Health Laboratory. They show how the crossing of the Nicol prisms on the polarising microscope blots out the glass fragments while allowing the sand or crystal to remain visible Provided manufacturers use good glassware and exercise proper care little danger need be feared from glass-packed foods, but these conditions are essential to public safety

HUMAN POLAR BODIES

Prof A F Dixon, of Dublin, has at last found a satisfactory polar body of a human ovum Some years ago Prof Arthur Thomson described what was probably a polar body in a woman's ovary, but the specimen was badly fixed and did not completely satisfy the histologists The fundamentalists will be discomfited They may be content that man should share his superfluity of naughtiness with mosquitoes, mandrils, and mammoths, but it must be very disappointing to have one assurance after another that he has not invented some peculiar mechanism of heritable reproduction known to himself alone, but proceeds along cytological lines of the most familiar type Anyone who is much more than momentarily interested in Prof Dixon's paper in the *Irish Journal of Medical Science* for April may well feel a little ashamed of himself; for if he is deeply moved by the discovery it means either that he is grossly anthropocentric or that he does not really believe in evolution As most of us look at everything from our own point of view, and as our faith is often weak, many will read the account and Prof Gatenby's comment with considerable attention

THE EPIDEMIOLOGY OF CHOLERA: A NEW CONCEPTION

THE significance of a difference of serological behaviour in organisms which are indistinguishable from one another in shape or in conditions of culture has long been a matter of dispute among pathologists The typing on serological lines of pneumococci and meningococci has not led to such striking clinical results as was at one time hoped, the agglutination tests carried out on the comma bacillus or vibrio of Koch, however, seemed to have a definite bearing on the pathogenicity of the vibrios At one time it appeared likely that the pathogenic bacilli alone showed specific agglutinability, and that those not possessing this power were not true cholera vibrios, though in every other respect indistinguishable from them Further investigations revealed the fact that sporadic cholera is very constantly associated with non-agglutinating vibrios A further complication is that no chronic carriers of agglutinating vibrios can be demonstrated, though spontaneous outbreaks of epidemic cholera have been observed to occur in many places where no history of immediate infection from any outside source can be obtained or be reasonably inferred A new conception of the epidemiology and endemiology of cholera was put before the Indian Science Congress, held at Lahore, in January of this year, by Dr J W Tomb and Captain G C Maitra They have since published their theory,[1] with a detailed account of the observations which led them to their conclusions In the first place, they observed that during the dry hot weather in the Asansol Mining Settlement vibrios were very numerous in the ponds or ground tanks frequented by the inhabitants of the Settlement for washing after defæcation When washing in these tanks was prohibited the vibrios gradually diminished in number and always disappeared after 12 to 14 days Efforts to isolate vibrios from the stools of those frequenting the tanks being a complete failure, the observers concluded that the ordinary peptone enrichment process for isolating vibrios from solid stools was unsatisfactory and after much experiment they devised an "open-bowl" method of cultivating vibrios from stools[2]

By means of this method they have been able to prove that in many parts of the mining settlement 35 per cent of the inhabitants are chronic carriers of non-agglutinating vibrios, though they have confirmed the absence of carriers of agglutinating vibrios noted by other workers The suspicion that agglutinability was a variable characteristic led to efforts to convert the non-agglutinating into the agglutinating types These proved inconclusive, but the reverse process was more encouraging Agglutinating vibrios in cholera stools permanently changed en masse after 12 to 14 hours into the non-agglutinating form when inseminated under natural conditions in a ground tank Laboratory cultures of Koch's vibrios changed into the non-agglutinating form only after 24 to 36 hours Dr Tomb and his colleague suggest that agglutinability is mainly an artificial property developed and fixed by laboratory cultivation Examination of the stools of epidemic cholera convalescents showed that 80 per cent of these convalescents became chronic carriers of non-agglutinating vibrios, the agglutinating form permanently disappearing from the stools within two to four weeks It has been a matter of common observation that during epidemics (due to agglutinating vibrios) non agglutinating vibrios invariably appear in great numbers in contaminated water supplies, the non-agglutinating vibrios disappearing pari passu with the disappearance of the epidemic

Dr Tomb and Captain Maitra conclude that the non-agglutinating vibrio (which is itself capable of causing clinical cholera) takes on the agglutinating characteristic under certain biochemico-physical conditions in the human intestine, the nature of which are at present unknown, and that this mutation or epidemic form is the cause of epidemic cholera Non-agglutinating intestinal vibrios in their opinion constitute the reservoir of cholera, both epidemic and endemic The theory is developed that the endemicity of cholera in any locality depends primarily upon the existence in the community of great numbers of (healthy) carriers of non-agglutinating vibrios, secondly, on the occasional conversion in the intestines of a proportion of these carriers—by some vital process—of the non-agglutinating vibrio into its mutation form the agglutinating vibrio, thirdly, upon the widespread and continued pollution of drinking water supplies with this mutation form through the unhygienic habits and customs of the people, and fourthly, upon the capacity of vibrios to persist or multiply in the drinking water supplies of the locality owing to climatic conditions, a vicious circle being thus established When once therefore cholera has been introduced into a community in widespread epidemic form, great numbers of chronic carriers of non-agglutinating vibrios remain—apparently for years—amongst whom cholera of the sporadic or the epidemic type may occur at any time, moreover, if drinking water supplies are habitually contaminated by the people then cholera will become endemic, provided that the climatic conditions are suitable for the survival and multiplication of vibrios On the contrary, where wholesale pollution does not occur, or where conditions are unfavourable to the persistence of vibrios in the drinking water supplies, cholera cannot become endemic; if epidemic outbreaks occur, they "fizzle out," as they are reported by Colonel Gill ordinarily to do in the Punjab during the hot dry weather[3] Dr Tomb and Captain Maitra predict that in the deltaic area of Bengal vibrios will be found to persist or multiply in the surface water supplies at the two periods of the year only when cholera is ordinarily epidemic there On the other hand, in the dry and arid regions of North-Western India the epidemic season of cholera is in general confined to the rains, since only during that season is there the necessary amount of surface water, as well as the necessary temperature (associated with the insanitary habits of the people) to make an epidemic of cholera possible Where the percentage of chronic carriers of non-agglutinating vibrios remains small, spontaneous outbreaks of cholera will be infrequent, and in such areas cholera, if it occurs at all, will be chiefly an imported disease The observers have been unable to ascertain by experiment whether or not the agglutinating vibrio immediately after it has lost agglutinability is still capable of conveying epidemic cholera, but from combined observations in the field and laboratory they conclude that the vibrio is capable of conveying cholera for some time after agglutinability has been lost, and a probable instance of this kind has been recorded by Chalmers and Waterfield[4] as having occurred in Gindha An additional factor, therefore, in the spread of epidemic cholera is the period of time which has elapsed between the contamination of drinking water with the agglutinating vibrio and its ingestion as a non-agglutinating vibrio by non-immunes.

THE BEHAVIOUR OF APES.

THAT useful and interesting journal, the *Quarterly Review of Biology*,[5] so brightly edited by Prof Raymond Pearl, in Baltimore, does not seem to be as well known in this country as it should be, especially among busy professional men who like to keep in touch with biological progress The first number of the second volume contains, among other notable reviews, a summary account by Dr R M. Yerkes and Miss M. C Child of what is known of the psychology and behaviour of the anthropoid apes which will help those who visit the Zoo on Sunday afternoons to orientate and arrange their interests, perhaps to contribute to the analysis of the ways of animals It is only in the last 15 years or so that serious attempts have been made to study the orang, gorilla, and chimpanzee in detail It has been done partly in captivity and experimentally, partly in the open where Mr T. A Barns and Mr. Benjamin Burbridge have made particularly valuable contributions under conditions in African forests which must necessarily be difficult There is much of interest about the animals' special senses their sight, for instance, seems to be separated by a wide gap from human vision, and Mrs Kohts had some trouble to make sure that chimpanzees can differentiate colours at all Some of the most notable observations have been made by Dr W. Kohler at the anthropoid station at Teneriffe, he thinks it is certain that the chimpanzee exhibits a degree of intelligent behaviour which in man would pass as evidence of insight and reasoning calculation Of language proper they have none Emotions have corresponding vocal expressions, and the sounds may possibly represent racial feelings or ideas but never those of the individual

THE PULSE-RATE IN DIPHTHERIA.

IN the February issue of the *New Zealand Medical Journal* Dr. I M Allen describes his observations on the variations of the pulse-rate in diphtheria in a paper based on the study of 132 consecutive cases He distinguishes three forms of pulse curve In the first, which was found in the mild uncomplicated cases, the fall in the pulse-rate occurred on the same day as the fall in the temperature or on the day following In the second form the pulse remained rapid for some days or fell at a longer interval than usual after the fall of temperature This form was usually found when antitoxin treatment had been delayed and was regarded by Dr Allen as indicating (*a*) increased elimination, (*b*) stimulation, (*c*) increased protection by the injection of more antitoxin The third type of pulse curve was characterised by a fall below normal after the fall in temperature, until the tenth to the sixteenth day when it rose by 20 or more This secondary rise, which occurred in 50 cases, or in 40 per cent of the series, persisted from a few days to six weeks and was attributed by Dr Allen to intoxication of the heart muscle Unlike most clinicians, Dr Allen is inclined to regard the local condition of the throat as of little value in forming a diagnosis, as he found that 60 per cent of his cases could not be diagnosed in this way. He maintains that a faucial condition accompanied by a comparatively low temperature and a high pulse should be suspected to be diphtheria and treated accordingly The relation of the variations in the pulse-rate to prognosis is next considered, the occurrence of a secondary pulse rise unless of short duration being generally regarded by him as a grave sign Early treatment by subcutaneous or intravenous injection—sufficient doses of diphtheria antitoxin combined in cases of mixed infection with antistreptococcic serum—is recommended, but, strange to say, no mention is made of the intramuscular route which many authorities regard as the most desirable in the treatment of diphtheria.

SYNTHETIC THYROXIN IN USE.

WE noted a week or two ago[1] the Harrison award by the Chemical Society to Dr C R Harington for his brilliant isolation of the active principle of the thyroid gland, leading to the synthesis of an iodised tyrosine derivative with similar properties The *Edinburgh Medical Journal* for April publishes a report of the striking results obtained in two myxœdematous subjects with a synthetic thyroxin prepared by Dr Harington and Prof G Barger The metabolic activity of both patients increased immediately and rapidly, by 26 per cent in one case and 48 per cent in the other, after doses of 14 mg each This gives figures of 1 85 per cent and 3 43 per cent per mg compared with the 2 8 per cent of the Mayo workers using natural thyroxin Corresponding rises in temperature and pulse-rate and decreases in weight accompanied the rise in basal metabolism Synthetic thyroxin should be more dependable than the crude thyroid in use to-day, and cheaper than the active principle isolated from the gland

ANTITYPHOID VACCINATION

IT has generally been assumed that dead typhoid bacilli are more efficient as vaccines if they are killed as gently as possible and in particular with as little heating as is possible In the last number of the *Journal of Pathology and Bacteriology* Dr J. A Arkwright suggests that this idea needs reconsideration and that the variety of the bacillus is much more important than the details of the preparation of the vaccine He worked chiefly with four variants of *B paratyphosus* A and less fully with the similar forms of *B typhosus* He distinguishes forms which grow in smooth colonies and are motile, those that grow in rough colonies and are non-motile, smooth non-motile, and rough motile varieties Smooth variants, whether motile or not, are much more virulent than rough forms The antigen associated with flagella and present in smooth and rough motile forms is destroyed by heat and therefore can have little effect on virulence On the other hand, the antigen which resists boiling is found in both the smooth forms and is absent from both the rough forms—i e, it is associated with virulence Following this out by dosing guinea-pigs with vaccines made from the different variants and then testing the resistance of the animals to intraperitoneal inoculation of live cultures, he finds that smooth motile and smooth non-motile forms make efficient vaccines, while both the rough forms are of relatively little value; and that smooth vaccines are at least as effective after being boiled as after being killed with the minimum of heat Hence the heat-resistant element in the bacilli is the important prophylactic agent The confusion has arisen largely from so many of the previous observations which were intended to be germane to the question having been made by measuring antibodies in the blood rather than actual resistance; experimenters have assumed that antibodies were a measure of immunity and have shirked the trouble or been unable to face the cost of direct tests of resistance Using ordinary cultures containing various and unknown assortments of the variants which are now being sorted out, the agglutination test as usually performed measures the agglutinins which are developed in response to the heat-labile element in the bacilli, the part of the antigen, that is, which is now found to be unimportant Dr Arkwright's discovery may well open up a new and fruitful field in vaccination It needs confirmation, his data are numerically not altogether convincing, and would hardly satisfy the criticisms of the bacteriologists' way of dealing with statistical problems which were made by Prof W W C Topley in his Harben lectures[1] His test doses, too, were very large and perhaps poisonous rather than infective But he has certainly made out a case which is worth hopeful prosecution And until some provision is made for the study of the botanical bacteriology which ought to be able to tell pathologists all they want to know about variants and races of bacteria, it will rest with the pathologist to work out this extremely important question of variation as well as to apply the results to medicine

INFLUENZA AS AN ENTITY

Writers on influenza often express doubt whether any such disease really exists or whether the infinitely various symptom-complexes which are thus described by clinicians are not in fact unrelated Since we do not know the nature of the responsible organism, the doubt is legitimate and salutary There is, however, a good case to be made out for the clinical unity of the conditions which are given the general name of influenza or *grippe* In their deductions from a recent big epidemic in Germany, H Taterka and M Landsberg[2] classify the disease into five forms according to the depth at which the respiratory tract is invaded, these are the severe toxic, the pharyngotracheal, the bronchitic, the bronchopneumonic, and the pneumonic The clinical evidence which they adduce supports the view that the diverse symptoms are due to a single organism acting at different levels, and associated with kinds of secondary infection. The local inflammatory symptoms are to be interpreted, as in all infective processes, as evidence of resistance, and the fulminating or "severe toxic" form is that which occurs when immunity is so low that little local resistance develops A reaction at the pharynx produces nose-bleeding, sore-throat, and persistent cough; at the bronchial level it produces bronchitic and asthmatic symptoms, whilst in the lungs it produces pneumonia, with a large range of characteristic complications One of these is an infiltration which may be present without febrile symptoms and persists for a long time, another is a fibrinous pleurisy rarely seen in non-influenzal broncho-pneumonia Dry pleurisy is often, because of its painfulness, the most conspicuous symptom Pulmonary abscess, gangrene, interlobular empyema, pleurisy with serous and hæmorrhagic exudate, induration and the outbreak of tuberculous lesions are also fairly common complications Nervous symptoms have been reported, for instance two French writers[3] recently described a cutaneous hyperæsthesia, which they have noticed in constant association with the tracheal form of influenza The skin of the face and head and sometimes of the shoulders becomes very painful, the lacrymal secretion is increased, the sense of taste is lost, and the pulse-rate rises considerably. These symptoms point, fairly certainly they consider, to an infection of the trigeminal and upper cervical nerves, simultaneous with infection of the mucosa

Whatever organisms are concerned in its causation, many authorities, like Rudolf Jaffé,[4] are satisfied that influenza may be safely diagnosed on pathological and anatomical changes in the respiratory tract alone Not only, he says, are the local changes highly characteristic—e g, the formation of pseudo-membrane in the lower part of the trachea—but the whole picture is such a motley that no other disease can produce anything to compare with it This is especially true when the lungs are involved The frequent coexistence of apparently unrelated symptoms may be due to the various secondary infections which are present in most cases of influenza, and their very presence is often sufficient to settle the diagnosis

A FRANCO-BRITISH ANATOMICAL CONGRESS

A joint meeting of the Association des Anatomistes and the Anatomical Society of Great Britain and Ireland was held during last week in the Institute of Anatomy at University College, London The Association, represented by the President, Prof A Brachet, of Brussels, and about a hundred members, with their wives, were met at a reunion at the University of London Club, Gower-street, by Prof G Elliot Smith, the President, and members of the Anatomical Society, on April 10th A full programme of about 120 communications and demonstrations occupied the time of the actual joint meeting, which extended over the next three days The morning and afternoon sessions had crowded audiences and were carried on under the chairmanship of the two Presidents The communications, which were for the most part of a highly technical nature, will appear in due course in the special journals of the various countries to which their learned authors belong It remains to be said that the austerities of scientific congress making were relieved on the social side, where already the visiting ladies had been put under the advisory care and guidance of a small ladies committee The Zoological Society threw open its gardens to the visitors on April 11th and the Tower and Hampton Court received them on other days A conversazione was held at University College on the evening of the 11th, when the fascinating exhibits were completed by the rendering of some charming songs by Miss Carey Foster On April 12th a reception was given at the Wellcome Museum of Historical Medicine in Wigmore-street, and was largely attended On April 13th the visitors were entertained to dinner by the Anatomical Society in the senior common room at King's College On the following day many members of the Association availed themselves of Prof J T Wilson's invitation to visit Cambridge and see something of the work of the schools of medicine there During the whole period of the Congress there was an excellent exhibit of anatomical appliances, models, and books

REST HOMES FOR RHEUMATIC CHILDREN

The Metropolitan Asylums Board decided at its last meeting to provide further residential accommodation for the treatment of London children suffering from rheumatic diseases, subject to the sanction of the Ministry of Health This is to be done by extending Queen Mary's Hospital for Children, Carshalton, to the extent of 350 beds, in addition to the unit of 60 beds primarily intended for research purposes which were set apart at the beginning of last year Consideration was given to utilising the admirable country site at Copthorne, near East Grinstead, purchased in 1914 for the erection of a sanatorium, but this proposal was negatived on account of the high cost of installation where no public services are already laid down The new accommodation will be for children of both sexes under 16 years of age suffering from subacute rheumatism, the later stages of acute rheumatism, rheumatic chorea, or rheumatic carditis including recurrent attacks It is admitted that there are in London not less than 10,000 children who have suffered or are suffering from rheumatic symptoms, and in a recent report to the London County Council Dr F N K Menzies stated that there are from 600 to 700 children absent from school for long periods on account of rheumatism, representing in fact some 25 per cent of chronic invalidity amongst school-children The experiment of sending these children o ordinary convalescent homes has not proved uccessful, the parallel between the problem of the heumatic and tuberculous child is fairly close and dmission to recovery homes requires a careful basis of selection The urgency of a rapid expansion of accommodation in such rest homes or hospital schools has been emphasised by the Subcommittee on Rheumatic Heart Disease in Children, appointed by the British Medical Association whose second report[1] has just appeared, and in this report the policy of concentration is advocated Each city, it is suggested, should seek to develop a kind of hospital suburb or colony at the best site available, and part of this development would be the hospital school or rest home which should provide for the rheumatic child treatment as long as may be necessary in the best possible environment This policy is now likely to have its fulfilment for London at Queen Mary's Hospital, Carshalton In the meantime, until the necessary building is completed, 56 beds at High Wood Hospital, Brentwood, are to be allocated temporarily for the treatment of these children

SILICOSIS AND THE HOUSES OF PARLIAMENT

A LAG is inevitable between the discovery of facts and their practical application Fifteen years have elapsed since the intimate association was recognised between inhaling silica dust in industry and a subsequent tendency to succumb to pulmonary tuberculosis, but in this country no definite campaign has been undertaken to abolish the silica dust risk, and with it one not inconsiderable group of deaths from tuberculosis So pronounced is the lag that we find the Government, through its Office of Works, embarking upon a contract, costing between three and four millions sterling and extending over some years, for refacing the Houses of Parliament with a freestone (Stancliffe stone) well known to generate toxic silica dust when worked The masons employed both at the quarry and on the buildings will be exposed to considerable risk

When the matter was raised in debate, the position was held that it was unreasonable to suggest that, while everyone else should be at liberty to use this particular type of sandstone, the Government should deny themselves the use of what was considered the most suitable and the best wearing stone that could be found for the purpose they had in view But surely the duty of Government should be first to set an example itself, and subsequently to interdict the use of so dangerous a stone The Ministry of Health spends ever more public money in its anti-tuberculosis campaign, and yet another Government Department chooses in the interests of architecture, it would appear, to expose a section of the community to risk Even from an æsthetic point of view the stone in question has little to recommend it for this purpose When it is used in an industrial atmosphere such as that of London, it turns a dull heavy black, which causes the onlooker to regret rather than to derive satisfaction from its lasting properties The Office of Works promises to take all precautions for the health of those engaged , the nature of the precautions are not stated Even if the new dust traps[2] for pneumatic tools could be adapted for stone carving, the masons appear determined not to use them Anyway the decision to use the stone was arrived at before any such palliative had been tried out It will be interesting to hear whether the Office of Works propose to adopt the preventive measures of the Miners' Phthisis Medical Bureau of South Africa, and to extend to the workmen about to be exposed to this unnecessary risk the provisions of the Workmen's Compensation (Silicosis) Act, 1918 Is it not possible, however, even at this late stage, to ask the architects to confer again, in the hope that some less dangerous material could be sought ? Portland stone was good enough for refacing Buckingham Palace

The Services.

ROYAL ARMY MEDICAL CORPS

Capt J W Pell to be Temp Capt , and temporarily relinquishes the rank of Capt

J W Dowzer to be Temp Lt

TERRITORIAL ARMY

C F Mayne, late Surg -Lt , R N , to be Capt

ROYAL AIR FORCE

E J T McWeeney is granted a short service commission as a Flying Officer for three years on the active list

Flight Lt (hon Squadron Leader) F E Wilson resigns his temporary commission

INDIAN MEDICAL SERVICES

The awards of brevets in peace-time is sparingly made and the honour is highly prized in the army The latest recipients of this distinction are Lt -Col A Spitteler, Commanding the Indian Station Hospital at Loralai, and Lt -Col J Norman Walker, the Viceroy's Surgeon

Dr Jamadar Abdur Rahim has been appointed Vice-Consul at Birjand in addition to his medical duties at Birjand Dispensary Lt -Col M MacKelvie has been appointed Civil Surgeon, Dacca, on return from leave Maj -Gen T H Symons, Surg -Gen with the Madras Government, has resigned his seat on the Council of State Maj S D Bilimoria has been appointed Asst Dir of Public Health, Ambala Circle, on transfer from the Military Department He relieves Lt -Col C A Gill, Asst Dir of Public Health, who has been holding this charge in addition to his other duties Maj K R Batra has been appointed Civil Surgeon, Kangra, relieving Maj H Chand Lt -Col Baird, civil surgeon, Allahabad, has been appointed Inspector-Gen of Civil Hospitals, United Provinces Lt -Col. Godfrey Tate, Inspector-Gen Civil Hospitals, United Provinces, has been appointed Surg -Gen , Bengal, vice Maj -Gen R Heard. Lt -Col G Hutchison officiates as Inspector-Gen of Civil Hospitals and Prisons, Assam Lt -Col C R O'Brien has been appointed Civil Surgeon, Mymensingh Capt S N Hayes has been appointed Professor of Midwifery, King Edward Medical College, Lahore, and Superintendent, Temporary Maternity Hospital, Lahore, vice Lt -Col R G Bott Lt G A Hill, Asst Dir of Public Health, Punjab (Technical) Epidemiology, has been appointed Asst Dir. of Public Health, Ambala Circle Dr C W B Normand has been appointed to officiate as Dir -Gen of Observatories, Delhi Lt -Col B R Dennis officiates as A D M S , Bombay District, vice Col Lloyd on leave

---

ROYAL MEDICAL BENEVOLENT FUND —At the last meeting of the Committee 43 cases were considered and £563 voted to 39 applicants The following is a summary of some of the cases relieved

Daughter, aged 60, of M R.C S who died in 1894 Has supported herself as a housekeeper until recently, when her mother's ill health obliged her to give up her post They live in one room at a rent of 10s a week, the joint income amounting to £94 per annum Fund voted £24

Widow, aged 61, of M D Durh who died in 1910 Married only nine months when her husband died Has supported herself by nursing and taking boarders until last year, when, owing to ill health, she was obliged to give up flat , now lives in a bed-sitting room at a rental of 10s a week Receives £22 from investments and gifts amounting to £75 Voted £24

Widow, aged 36 of M R C S who was killed in an accident last year Left with two children aged 7 and 2½ Asks for temporary help until her late husband s estate is settled She is resuming her nursing and hopes to be able to manage later to support herself and children Voted £20

M D Durh , aged 70 Married One son, who is allowing his father £5 a month Has only made £50 from locums this last year, and was taken ill in June Through the kindness of a friend was given £150 for his own and wife's expenses and now asks for help during convalescence Voted £15

Daughter aged 60, of M R C S who died in 1899 Applicant and her sister left business some years ago to look after their aged mother To meet expenses they let part of their house and also took boarders Joint income investments £22 boarders, £129, letting £70 Mother had Old Age Pension and an Epsom Pension Rent and rates amounted to £75 Voted £26

Subscriptions may be sent to the Hon Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, W 1

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CCXX

TREATMENT OF VARICOSE ULCER.

Varicose ulcers owe their characteristics to the faulty circulation of the blood through the limb on which they occur. The dilated and inelastic veins allow the venous blood to stagnate and the defective blood flow causes malnutrition of the limb. The subcutaneous veins are generally most diseased and, therefore the skin and subcutaneous tissues suffer most, but the whole limb is affected to a greater or less extent as is shown by loss of tone of the muscles and ligaments and excess of extravascular fluid. In uncomplicated cases of varicose veins this defect of the circulation is only present when the foot is below the level of the pelvis, when the patient is horizontal, or the foot raised, the venous return is not impeded and there is a good circulation in the limb.

The faulty nutrition of the limb predisposes to indolent ulcer in two ways. (1) The skin becomes more susceptible to injury and infection. (2) The process of repair is hindered. When an injury occurs, and sometimes without a visible wound, the skin becomes inflamed and phlebitis and lymphangitis cause occlusion of the vessels and still further impairment of the circulation. There is no direct connexion between the extent of the varicose veins and the susceptibility to varicose ulcer. A patient may have large varicose veins and yet maintain a good enough circulation to keep the skin healthy, while a patient with little apparent varicosity may have serious malnutrition of the skin. Phlegmasia alba dolens and thrombosis of the femoral veins may lead to lesions that are indistinguishable from varicose ulcer.

When an ulcer has appeared secondary changes are set up. Septic infection occurs in the skin and surrounding tissues and they become hard, œdematous, and inelastic; cicatrisation, the extent of which depends upon the severity of the septic infection, leads to further impairment of the circulation and delay in healing. Long-standing and improperly treated ulcers may cause these secondary changes to affect the skin and subcutaneous tissues of the whole circumference of the limb and to extend from the knee to the foot. The infection may spread through the deep fascia by the veins and lymphatics causing adhesion of tendons to their sheaths, myositis, periostitis and occlusion of the deep vessels, and trophic changes in the foot. Varicose ulcers are not, as a rule, painful. Pain is generally a sign of phlebitis or inflammation under the deep fascia.

Varicose ulcers have to be distinguished from indolent ulcers occurring in a scar which is surrounded by healthy skin; infective ulcers such as those due to syphilis, tubercle, &c., ulcers associated with disease of the underlying bone, and carcinomatous ulcers which are generally, but not always, due to malignant changes in an old neglected varicose ulcer.

Preventive Treatment.

All patients with varicose veins should sleep with their feet raised above the level of the pelvis. This is most easily effected by placing under the mattress a skeleton wooden wedge the same width as the bed, seven inches high at the bottom and increasing to nothing at the level of the patient's hips. Such a wedge can be easily made of wooden laths fastened to two triangular pieces of wood. No other treatment is needed, unless there are signs of defective circulation such as atrophy of the skin, œdema after standing, and loss of tone of muscles and ligaments. If these signs be present the patient should be advised to lie with the feet raised for an hour in the middle of every day, and to wear a support such as crepe bandages or a well-fitting elastic stocking reaching from the toes to half-way up the thigh. The stocking should be made in two parts, one reaching from the toes to the tubercle of the tibia, and the other from the middle of the thigh far enough down to overlap the upper edge of the lower part. If the stocking is in one piece it constricts the veins about the knee during movements of the limb. The support should be put on each morning before the leg is put out of bed—i.e., before the veins become distended with blood.

Small Early Ulcers

Any graze, pustule, or inflammation of the skin, no matter how apparently trifling, should be regarded as serious if it occurs in a limb that shows signs of defective circulation. The patient should be advised to lie up entirely with the foot raised until the lesion is healed. The sepsis should be treated with warm boric compresses, which should be always moist and not applied too hot, the skin being easily injured by heat. When the ulcer is clean it should be covered by a dressing that does not require changing too often. Even the most careful dressing tends to damage the newly formed epithelium. Unna's paste, to which 1 part in 16 of boric acid or 1 part in 8 of balsam of Peru has been added, is a very satisfactory dressing. In these small ulcers it does not need changing more than once a week, the ulcer will generally heal in a fortnight.

When the ulcer is healed it is advisable for the patient to lie up for a further week or more, according to the size and thickness of the scar, and during this time gentle massage vibro massage, and radiant heat (not more than 180° F.) are valuable aids to getting a healthy scar. When the patient gets about again the preventive treatment outlined above should be carried out. It is not advisable to perform any of the many operations on the veins that have been suggested. None improves the circulation in the limb and many make it worse.

Large or Chronic Ulcers

In these cases the secondary changes referred to above are always present. For this reason the methods of treatment that would be applied to large and chronic ulcers elsewhere are not applicable. If the ulcer be excised its site will still have the imperfect circulation that is the initial cause of the condition; and for the same reason sliding flaps and tube grafts give unsatisfactory results. The treatment should be directed to prevent further impairment of the already defective circulation by extension of infection, and to promote rapid healing with minimal scar formation. The patient should rest with the foot elevated, warm boric compresses being applied until the ulcer is clean and the erythema has subsided. This does not generally take more than a few days and then, if the granulations are bright red and healthy in appearance, healing can be hastened by covering the surface of the ulcer with Thiersch grafts, which should be taken from the arm rather than the thigh, the blood-supply of the latter often being impaired. The grafted ulcer can be covered with a dry gauze bandage, which should not be moved for five or six days. When the grafts have taken Unna's paste or a mild antiseptic dressing should be applied, and not changed more often than necessary.

If the ulcer be very slow in cleaning or if the skin at its edge forms a hard dense fibrous ring, the granulations are generally purple in colour and pulpy and unhealthy in appearance. Such an ulcer may be curetted and the fibrous ring removed. To do this properly an anæsthetic is necessary, and all the tissue down to the deep fascia should be removed. Boric compresses are then applied until healthy granulations form, and these may then be covered with grafts. This method of treatment takes a long time, often many weeks, and it is only successful in a proportion of the cases in which it is tried. Healing may be hastened by ultra-violet radiation, given as a graduated general body bath, during the period of cleaning the ulcer concentrated local applications of ultra-violet radiation may be given, but only minimum doses must be given since the poorly nourished skin readily vesicates

The patient should be kept at rest after the ulcer is healed, and the scar treated in the same way as those of small early ulcers Freedom from recurrence depends largely on the length of rest after healing and on the care with which after-treatment is carried out

Intractable Ulcers —If the ulcer has been present or recurring for many years and is situated in a large area of discoloured indurated skin, and particularly if the deep structures have been affected to such an extent that the ankle is almost fixed, it is often not worth while to undertake the many months treatment necessary to heal such an ulcer The resulting scar breaks down almost as soon as the patient gets up, and returns to the same condition as when treatment was started Such ulcers should be treated by the ambulatory method, the object then being to prevent them from getting worse rather than to persuade them to heal

Amputations —In cases in which suppurative phlebitis has occurred below the deep fascia and the ankle is fixed by matting of the surrounding structures, it is often impossible to get the ulcer clean, and no treatment will obviate the necessity of frequent dressings The inconvenience of this and the crippling resulting from the deformity may be so severe as to make amputation necessary It should be performed through the lower third of the thigh; the badly nourished tissues below the knee make a poor stump

Ambulatory Treatment

Patients are often unable to lie up for the time necessary to heal a varicose ulcer There is then always a serious risk of development of the secondary changes above referred to, even if they are not already present It is difficult to impress on patients the seriousness of what appears to be a slight graze or septic spot, but they must be made to understand that it is only by prolonged and careful treatment which they themselves must conscientiously carry out, that they can be spared a lifelong disability The preventive treatment outlined above should be adopted and the ulcer cleaned by boric compresses — a long week-end in bed is a great help in doing this. Unna's paste should then be applied from just above the malleoli to the tubercle of the tibia (no matter how small the ulcer may be) and this should be changed about once a week Crepe bandages or an elastic stocking should then be put on over the dressing.

Note on the Application of Unna's Paste

Zinc and gelatin paste of the B P C (commonly called Unna's Paste) is often wrongly applied The container should be stood in water just warm enough to melt it (about 100° F), and a bandage three inches wide prepared of a roll of white gauze four layers thick, or of soft crinolin quite free from starch or dressing The ulcer to be dressed should be clean, and the skin around should be washed and dried by a spirit lotion which should be allowed to evaporate The part to be covered should then be painted with a thick coat of the jelly, by means of a brush or cotton-wool swab, and immediately covered by a single layer of the bandage, which must be evenly and firmly applied It should be applied firmly enough to make the jelly bulge through its interstices, and to avoid creases and ridges in the bandage it may be cut into lengths as often as necessary as it is bound on Another thick coat of jelly is applied and then another layer of bandage until about six layers are in position Nothing should be allowed to touch the dressing until it is firmly set It may then be covered with a light bandage, unless the patient is going to wear a crepe bandage or elastic stocking over it To remove the dressing it should be saturated with warm water

AN OUTBREAK OF TYPHUS.

BY ANDREW DAVIDSON, M D GLASG , D.P H ,
DIVISIONAL MEDICAL OFFICER, PUBLIC HEALTH DEPARTMENT, GLASGOW ,
AND
ROBERT CRUICKSHANK, M D ABERD, D P H ,
ASSISTANT RESIDENT PHYSICIAN, BELVIDERE HOSPITAL, GLASGOW

General

A SMALL outbreak of typhus occurred in Glasgow during the later days of July and the first two weeks of August, 1926, and for several reasons certain of its aspects are worth recording

The disease has not appeared in epidemic prevalence in this country since the middle of last century, and its gradually diminishing incidence within recent years has given rise to a general impression that the disease is smouldering before total extinction The low incidence is reflected in the very few references to the disease in recent British medical literature, and what references there are relate chiefly to epidemics in Eastern Europe Typhus was present in many Eastern European countries during and immediately after the war, and spread as far westwards as Holland, Spain, and Portugal The distribution of the disease in Britain is interesting, and Table I shows the number of cases of typhus and the number of areas affected for each year since 1919, when the disease was prevalent in Europe :—

TABLE I —*Typhus in England (E) and Scotland (S) (1919–25)*

—	1919		1920		1921		1922		1923		1924		1925	
	C	Aa	C	Aa	C	Aa	C	Aa	C	Aa	C	Aa	C	Aa
(E) ..	3	1	—	—	—	—	13	4	1	1	8	1	—	—
(S)	38	4	74	5	1	1	20*	4	2	1	—	—	14	1

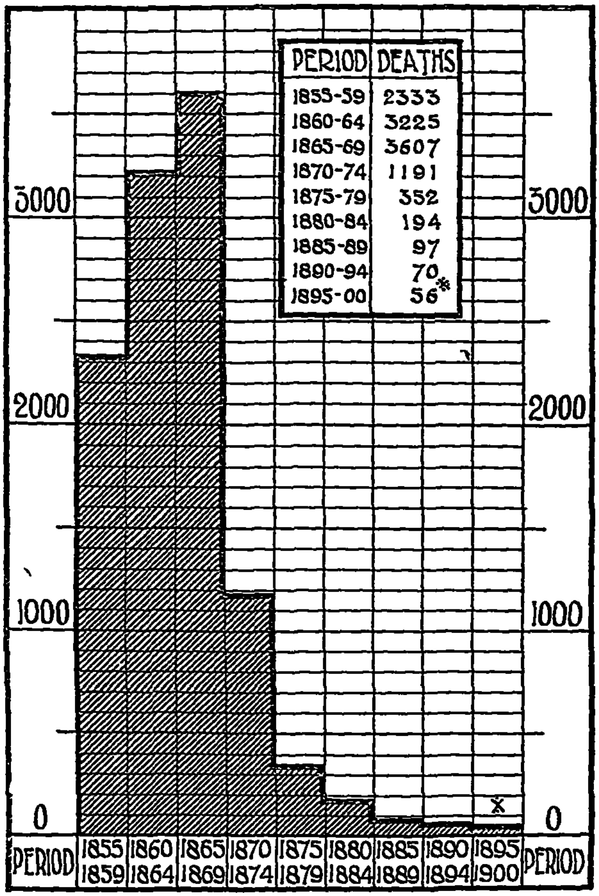
C =Cases Aa =Areas affected

* This figure does not include an outbreak of typhus in the Isle of Raasay, Skye

A prominent feature of Table I is the relatively low incidence of the disease in England compared with Scotland during the years 1919–25 inclusive Another feature is the distribution of infected areas in those years when typhus was more highly prevalent In *Scotland*, since 1919 these areas are representative chiefly of the west of Scotland, the majority of cases occurring in Glasgow, Greenock, and Paisley In 1925 the 14 cases reported were confined to Greenock. Since the outbreak in Glasgow during August, 1926, cases of typhus have been reported from Dumbarton, Port Glasgow, and Stranraer, towns situated in the south-west of Scotland In *England*, the two outbreaks since 1919 have occurred in the north-western district In 1922, out of 13 cases reported in England, Birkenhead was responsible for 11 cases An outbreak in England in 1924 comprised eight cases occurring in St Helens It is remarkable that the distribution of typhus during the period 1919–26 has been along the western seaboard of Britain, and with the exception of the outbreak in Skye during 1922, has been confined to the south-west of Scotland and north-west of England The proximity of these districts to Ireland—a recognised endemic centre of typhus—may explain the appearance of the disease in these parts.

The intimate association of typhus with overcrowding, hardship, and poverty arising from causes such as war or famine has been recognised since early times, but it is now realised that these factors are only contributory to the part played by body vermin in the transmission of the disease There exists in this country the mechanism for the spread of the disease, and it would appear that only the infecting virus, whose presence is represented by the above-recorded outbreaks, is necessary to produce an epidemic of the disease The early clinical recognition of the disease and a full appreciation of the part played by body vermin in the transmission of the infection are the important factors in the control of typhus

FIG 1.



Graph showing typhus fever in Glasgow Total number of deaths in five-yearly periods from 1855–1900 Six years are included in the period indicated by an asterisk.

So few are the cases occurring in Britain that many medical practitioners are unacquainted with the clinical manifestations of the disease In addition, sporadic cases of typhus, like other infectious diseases —and notably cerebro-spinal fever—are atypical and lead to difficulties in diagnosis, the disease tending to breed true only in epidemic periods These facts suggest sufficient reason for publishing the following notes, for the undiagnosed or missed cases of typhus is frequently the cause of the appearance of the disease in epidemic proportions The outbreak in Glasgow was confined to eight cases, and five of these were admitted to hospital before the development of the rash, two others on the first day of the rash It was therefore possible to study the disease from its earliest stages, which permitted of a complete and detailed survey of the clinical features Certain important laboratory investigations were also carried out

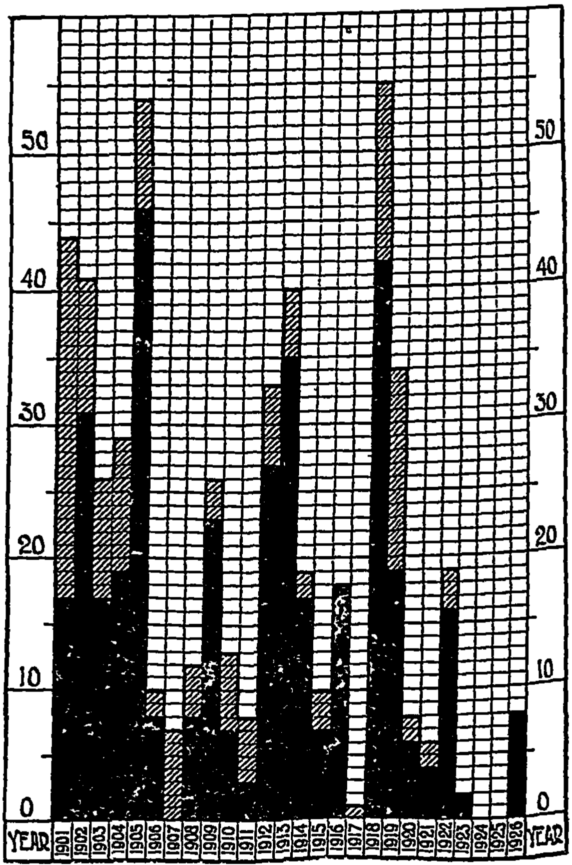
History of Typhus in Glasgow.

In 1818 Glasgow—a manufacturing city of 145,000 inhabitants—experienced its first great epidemic of typhus The disease reappeared in epidemic prevalence in 1837, 1847, and in 1851–52 After the last of these epidemics there was a period during which the disease declined in the city, and admissions for fever to the Royal Infirmary in 1859 were fewer than in any of the preceding 35 years, notwithstanding the enormous increase in population during that period. Reliable statistics relating to typhus are available since 1855, and the history of the disease in the city since that year may be divided into two parts—namely (1) 1855–1900, and (2) 1901–26

(1) (1855–1900) —While the actual numbers of cases occurring during the earlier years of this period are not known, accurate statistics of deaths from typhus since 1855 are available The figures form a fairly accurate picture of the incidence of the disease since that year, and the deaths are shown in five-yearly periods on Fig 1 This graph shows a definite and sustained diminution of the incidence of the disease in the city

In the 'sixties of last century the whole "Sanitation" energy concentrated on a struggle with typhus, and hospital accommodation was first provided by the municipality as a counter attack to the ravages of the disease In 1865 the first Municipal Fever Hospital was established for the isolation of cases of typhus, and from Fig 1 it will be seen that following the quinquennial period 1865–69 a definite reduction in incidence of the disease occurred This reduction was not wholly due to the isolation of the patient, but also to the administrative measures taken to prevent overcrowding, which resulted in a higher standard of personal and domestic cleanliness Typhus had therefore occurred in extensive epidemics in the city during the nineteenth century, although for the last 25 years of that century the disease showed no tendency to assume large epidemic proportions

FIG. 2.



Graph showing cases of typhus fever in Glasgow for years 1901–26 Grouped cases indicated in solid black

(2) (1901–26) —During the period 1901–26 the disease continued to show a low incidence in the city,

and on Fig 2 the *actual cases* occurring in each year are represented It is necessary to explain that the city extended its boundaries to include adjacent burghs in 1912, so that the incidence of the disease after that year is calculated on a much increased population and is not comparable to the incidence preceding that year Until 1924 typhus was endemic in the city, but during the years 1924 and 1925 no known cases of the disease occurred in Glasgow The period of freedom of the city from this infection was actually longer than two years, for the two cases registered in 1923 occurred in January of that year, whereas the 1926 outbreak occurred in August—i e, three and a half years afterwards In the graph (Fig 2) the grouped cases are shown in black, whereas sporadic cases are represented by shaded areas A group of cases consisted of two or more cases associated with one another The highest number of cases occurring in one group was 14 during the year 1918 Each black area on the graph may represent several small groups of cases; for example, in 1910 there were two groups of infection in April followed, not until four months later, by isolated single cases in districts widely separated, in 1912, of the 43 cases registered, 23 *occurred in four separate foci, but* in the same group of streets These outbreaks were no doubt inter-related, although inquiry failed to demonstrate any association Later in this year there occurred cases in three families not associated with the former cases or with one another; in 1913 six areas in different parts of the city were affected, four of which were found to be associated In the case of two areas there was no connexion, although there was the suggestive fact that the original case was a dealer in old clothes, and, in 1918, there were eight groups of cases occurring at different periods throughout the year The first group consisted of 14 cases in the same district and spread over a period from the end of January to the end of March of that year These eight groups of cases occurred in different parts of the city

In the specific years mentioned above typhus occurred in small groupings of cases at different parts of the city and also in sporadic form Although these years have been mentioned as examples the same picture of the disease presents itself in nearly all the other years forming the period 1901–26 During this period 87 groups of cases occurred in Glasgow, and Table II shows an analysis of the diagnosis of the first cases in each group —

TABLE II

Typhus	51	Other diseases	9
Enteric fever	22		
Pneumonia	5	Total	87

In 36 groups therefore, the diagnosis of the primary case was missed The chief difficulty was apparently to distinguish typhus from enteric fever The nine cases classified in the table under "Other diseases" comprise two cases of influenza, two of scarlet fever, one of nephritis, one of diphtheria, and three notified as "Undefined fever"

History of the Outbreak

This small outbreak of typhus was limited to eight cases and occurred in one of the lower working class districts of Glasgow Seven patients, including the first recognised case were members of the same family six of whom resided in the same house, the seventh being a married daughter who frequented the house, but lived some distance away The eighth patient, a friendly neighbour, had nursed the first recognised case prior to his admission to hospital

The first reported case, G B a male, aged 25 years, had been admitted to a general hospital on July 29th, 1926—his eleventh day of illness—with a diagnosis of nephritis He had a history of headache, joint pains and a mild delirium of two days' duration A rash was present on admission and a suspicion of typhus raised He was transferred to Belvidere Fever Hospital for observation In this institution he was restless and talkative with dry furred tongue and an offensive breath due to oral sepsis The pupils were not contracted and reacted smartly to light and on accommodation, and there was no suffusion of the eyes The facies did not suggest the "bloated" facies of typhus There was a generalised petechial rash of a *bright-red* colour with some subcuticular mottling It was extensively distributed over the trunk, arms, and legs but exempted the face On the hands and feet it presented a purplish appearance, but even there the elements were discrete. The rash could not be regarded as absolutely typical of typhus and the constitutional disturbance was not in proportion to the extent and intensity of the eruption Some nuchal rigidity and a slight but definitely positive Kernig sign suggested a meningeal condition Lumbar puncture gave a slightly turbid fluid under normal pressure, which, when examined, showed an increase of globulin and a cellular exudate consisting more of polymorphs than lymphocytes, but no organism was found The urine contained albumin but no other abnormal constituent The case was doubtful clinically, but the Weil-Felix reaction was positive

When the suspicion of typhus was raised the patient's home was visited

Two members of his family a girl, aged 18 years, and a boy, aged 10 years, were suffering from headache and malaise, they were removed immediately to Belvidere Hospital for observation The house of a married sister, aged 25 years, was visited and this woman was confined to bed with headache and a slight temperature She also was removed to hospital for observation The remaining contacts from both houses were transferred to a reception house On July 31st—i e, the day following the admission of the above four cases to hospital—two sisters of the original patient, aged 14 years and 13 years were transferred from the reception house to Belvidere Hospital These children were apparently well, but had developed elevations in temperature On August 1st another sister of the first case, aged 20 years, a maid in a local hospital, was admitted to Belvidere Hospital with a temperature of 101° F and an early suspicious rash One of the numerous contacts kept under observation was admitted to hospital on August 6th with a temperature of 103° F and a slight rash This eighth patient was a woman, aged 50 years, who had been in direct contact with the original case, having nursed him before his admission to hospital

All the above cases showed definite evidence of typhus several days after admission to hospital

Source of Infection

Extensive inquiries were made with a view to tracing the source of infection of these cases, but no definite conclusion was reached

The history of previous illness in the family revealed a few suggestive circumstances which could not be entirely dissociated from the later appearance of typhus in the household

The father of the family, aged 50 years, died in a local general hospital on July 16th from an illness whose nature was somewhat obscure This illness commenced with rigor, headache, and sickness, on admission to hospital on July 5th the patient was semi-comatose and complained of violent occipital headache There was some rigidity of the neck, contraction of the pupils, and congestion of the face The reflex responses were sluggish and there was a positive Kernig sign From the date of admission to hospital to the date of death there was no evidence of rash and no cases of typhus occurred in that hospital From post-mortem examination the cause of death was certified as "pneumococcal meningitis" In addition, the mother of the family had also suffered, but had recovered from an indefinite illness lasting eight days During the earlier part of June she had been confined to bed with *occipital* headache and sickness A Weil-Felix blood reaction in her case was negative, but this test was performed six weeks after the onset of her illness There had been no illness in the family antecedent to that of the mother

It is difficult to dissociate the illness of the father from the definite typhus from which seven of the family suffered

From an administrative point of view the illness of the father was treated as typhus No definite information of the deceased father's movements could be obtained The mother stated that he had been unemployed and had never been away from the district where he lived The movements of the mother and of the first recognised case did not assist in detecting the source of infection None of the family had been outwith Glasgow, and so far as is known no member had been in contact with a case of typhus The last known case of the disease in Glasgow *occurred in* January 1923, and in another district of the city It has been suggested that the virus of typhus may pass through generations of lice and reproduce the disease in the same locus at different times In this outbreak the infected houses were situated in streets which had not previously been infected The nearest previous case of typhus occurred in an adjacent street in February, 1922 —i e , four and a half years previously—and there was no association between the family infected in 1922 and the family infected in August, 1926

Glasgow and Ireland have been intimately related in the history of typhus In the 1846 epidemic affecting the larger cities of Britain, there is abundant evidence that the disease was imported from Ireland In 1913 the outbreak in Belfast was associated with the sale of old clothes imported from Glasgow where several cases of the disease had occurred Again, Greenock has been an endemic centre of the disease for several years The source of infection in the Glasgow outbreak of 1926 is obscure and has no relationship, at least, to Dublin or Belfast The last case of the disease in Dublin occurred on April 30th, 1926, and was a contact from a neighbouring urban district, whilst no cases of this infection have occurred in Belfast for several years

Clinical Notes on Cases

These notes are a summary of a comprehensive study of eight cases of typhus The extensive literature on the clinical aspects of typhus in this country deals with the disease as it occurred a decade or more ago No marked change in type falls to be recorded, but bearing in mind the wide variations in the types of other infections which have occurred in a like period, a brief portrayal of the clinical picture of the present series may not be amiss

Age —In the family of seven the ages ranged from 10 to 27, and the eighth case was a woman aged 50

Sex —Two of the patients were male and six female

Stage of Invasion —The fever was ushered in with rigor and severe frontal headache in two cases Two other patients complained first of headache, backache, generalised pains, and an " out-of-sorts " feeling not sufficient to confine them to bed for two to three days, while in the two youngest patients the first evidence of infection was an elevation of temperature The headache and backache persisted during the invasion stage and was frequently accompanied by nausea and sickness Nervousness amounting to hyperexcitability was noticeable in the younger cases

Rash

(*a*) *Description of Rash* —The rash appeared on the fourth to sixth day of illness, except in one case where it was noted on the second day of pyrexia It consisted at first of pinkish-red maculo-papules, chiefly intradermal and just appreciable to the finger One case (M B , 15 years) had a papular eruption on the wrists and both palmar and dorsal aspects of the hands comparable to the papular eruption of small-pox. The maculo-papules later became more macular and of a larger size with an irregular margin fading into the surrounding skin The pinkish-red colour of the rash at this stage resembled more the rash of rubella than that of measles The spots faded readily on pressure, varied in size and shape, tended to become more profuse and confluent on the extremities and back, and remained more discrete and smaller on the abdomen, where the lesions were brighter and stood out well against the whiter background Later lesions of indefinite outline and more purplish in colour developed in the deeper layers of the skin Subcuticular mottling aptly expresses this appearance In the progress of the exanthem there was a gradual recession of the rash into the deeper layers, as shown by the successive stages of papule, maculo-papule, macule and subcuticular lesion

(*b*) *Colour of Rash* —The colour varied from bright reddish-pink (maculo-papules) to more delicate pink (macules), while the subcuticular lesions were more purplish in hue Later the macules became dull reddish-brown, were more injected, and disappeared less readily on pressure In the more severely ill patients petechiæ developed in the centre of pre-existing macules The purplish, subcuticular element was best appreciated on the extensor aspects of arms and legs and in the flanks The rash gradually faded, became dirty brown in colour, showed no tendency to desquamate, and at this stage was difficult to differentiate from the staining of a scarlatinal erythema or other intense eruption. Later, such elements as remained were isolated brownish spots, not unlike freckles There was a tendency, most noticeable in the milder cases, for the rash to vary in intensity from day to day and even from hour to hour

(*c*) *Distribution of Rash* —The papulo-macules were first noted on the abdomen and, scantily, on the chest Soon after they appeared on the entensor surfaces of the forearms, where the eruption early became quite profuse and was present there even when the rash generally was quite scanty The rash spread rapidly to the lower limbs, the lesions being most profuse on the buttocks and along the anterior and extensor surfaces of the legs, and in the course of six to eight hours it had covered the whole body, exempting only the face The areas most extensively involved were the back in the interscapular region and, in the female, the breasts, particularly around the nipples and in towards the axillæ, down the sides, above the iliac crests, and extending laterally towards the lumbar region , on the limbs, the buttocks and extensor aspects of the forearms and legs were most affected. The upper arms, the groins and axillary folds were but little affected when the rash was scanty This is scarcely in agreement with the usual teaching In one patient papules were noted on the forehead and neck, spreading over the angle of the jaw to the cheeks

Relationship of Intensity of Rash to Age and Severity of Illness —Generally speaking, the younger the patient the less intense was the rash. In the case of W B (male, 10 years) the rash was evanescent, lasting only two days, varying in intensity during that period, and leaving very little staining In J B (female, 13 years) the rash was generalised and well developed, but less confluent than in the older patients and tended to fade more quickly with less staining and no petechial elements The most intense rash was that of the original case who certainly was not the most ill of the patients In his case the eruption was much brighter and more hæmorrhagic than any of the others and naturally persisted longer Petechiæ were noted in Mrs E R (female, 25 years) and S B (female, 20 years), both of whom were extremely ill The prognostic value of the hue, brighter in more favourable cases, dusky and purplish in very ill cases, was exemplified in Mrs McG , the only fatal case, whose rash, although generalised, was never more than a dull purplish mottling In all cases the rash developed before the Weil-Felix reaction became positive

Hyperæmia of the Skin —A striking feature of the cases was a tendency to a sodden, hyperæmic skin, best appreciated on the dependent parts—e g , on the back—and shown by the marking of the skin by the bed clothes and the presence of large erythematous blotches on pressure points This hyperæmia was noted by Murchison, and is in contrast to what is found in most other acute febrile conditions

Advance Stage —With the appearance of the rash there was greater constitutional disturbance, the temperature reached its highest level, and the patients looked acutely ill. The outstanding feature was great drowsiness and lethargy, particularly noticeable in the younger patients, who, from being comparatively bright and lively, now became absolutely listless and apathetic, and relapsed into their drowsy state as soon as they were left undisturbed Later, when the rash was fading, there was an amelioration of the symptoms and a fall in temperature in the more favourable cases. In the more severely ill patients, however, the temperature kept continuously elevated, the pulse became more rapid, numbering over 120 per minute, and the gravity of the patient's condition increased until crisis was reached about the twelfth to fourteenth day

Crisis —In no case was the crisis dramatic or sudden , it was more of the nature of a rapid lysis than an actual crisis Although the temperature fell from 103° F. or thereby to normal in 36 to 48 hours, the patients, while they professed to feel much better, still looked fairly ill and remained in their drowsy condition for some days after the temperature commenced to drop In the younger children (W B , 10 years, and J B , 13 years) the crisis occurred on the tenth and eleventh days, and in the others, except Mrs E R , on the twelfth to fourteenth day. From the thirteenth till the twenty-fourth day of infection Mrs E R was exceedingly ill and prostrated She lay in a low, typhoid state, unable to help herself or ask for anything, muttering frequently, and talking incoherently The tongue was very dry, cracked, and covered with a blackish fur , the eyes were dull and glazed and the facies bloated and expressionless From the fifteenth day subsultus tendinum was present, at times to an extreme degree, while on the night of the sixteenth day there was a sharp rigor followed by a collapsed state for 12 hours At night she was restless and sleepless and for two days there was a smouldering, resentful look in the eyes significant of impending delirium ferox The pulse was soft, irregular, and increased in rate to 130–140, but from the sixteenth day there was a gradual fall of temperature until on the twenty-third day of illness it reached normal. Convalescence was rather protracted, several weeks elapsing before the patient had regained sufficient strength to sit up

Temperature and Pulse —The temperature curve was of parabolic type, commencing from about 100° to 101° F. and rising steadily with slight remissions to 104° on the

FOUR REPRESENTATIVE TEMPERATURE CHARTS.

FIG. 3.

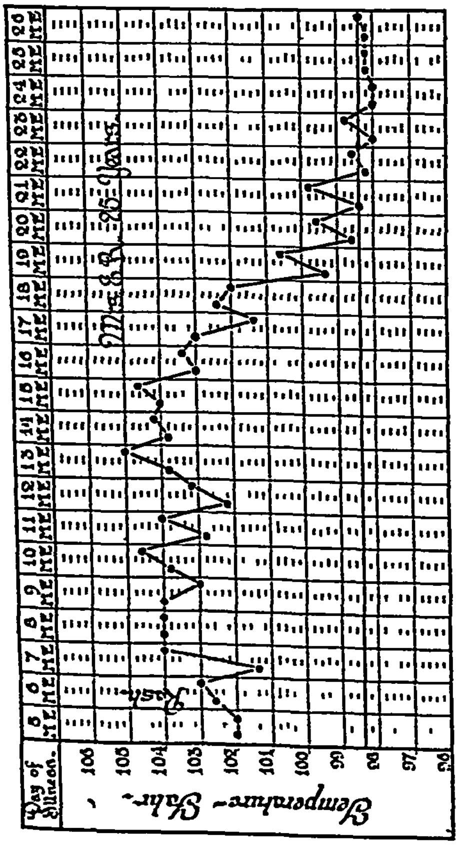


FIG. 4.

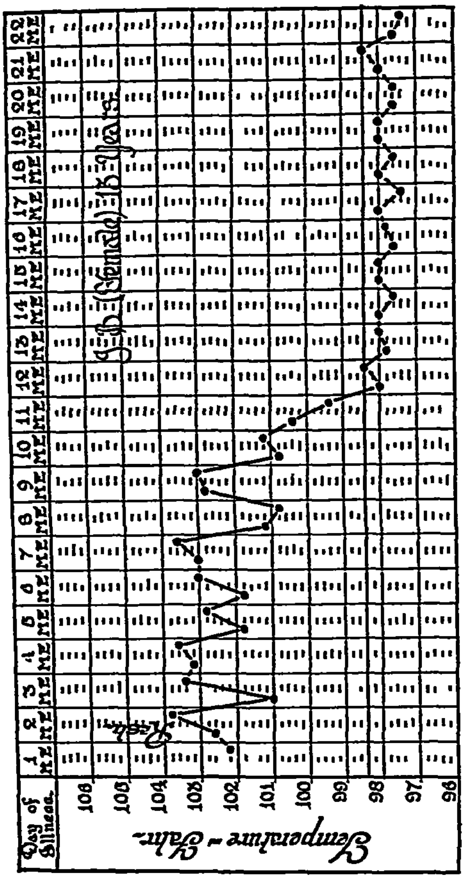

FIG. 5.

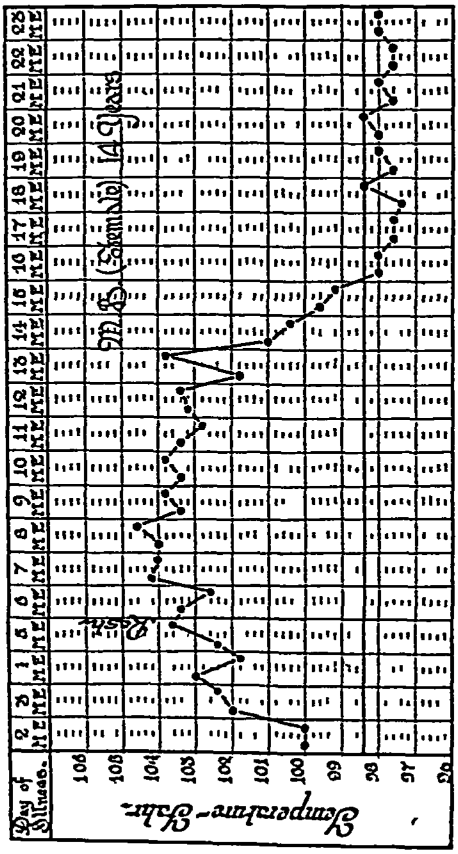

FIG. 6.

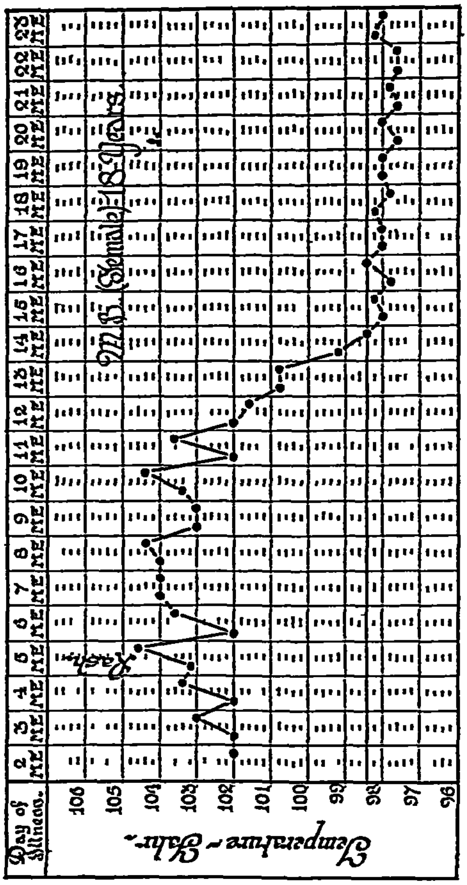

fifth or sixth day of illness—the active eruptive period During the second week the temperature tended to fall a little in the more favourable cases, ranging around 103° and dropping on the thirteenth or fourteenth day to reach normal two days later This tendency to fall off during the second week of the illness was regarded by Claude Ker[1] as a favourable prognostic sign Whereas in the severely ill patients the temperature was more or less continuous, in the milder cases it tended to be remittent in character The temperature chart of Mrs E R resembled that of a case of enteric fever in its slow lysis The pulse-rate rose with the temperature and ranged from 110 to 120 in most of the cases, but in E R 's there was an acceleration to 130 which seems to warrant a bad prognosis The pulse in the early stages was full and bounding, but later became softer and more dicrotic The pulse-rate again fell with the temperature (see Figs 3, 4, 5, 6)

Respiratory System —Bronchitis and pulmonary symptoms have been regarded as a feature of typhus in previous outbreaks, but in the present series only one case developed bronchitis The three most acutely ill patients showed a degree of hypostatic congestion during the crisis

Facies —In the early stages, and in the milder cases throughout the entire illness, there was no coarsening of the features nor tendency to congestion of the facies with pink-eye, usually described in typhus, but in the more severely ill patients after the eruption there was a definitely *congested "heavy"* facies with conjunctival injection and a dull, stupid expression, well described by the word "bloated"

Alimentary System —In all cases there developed a dry parched dirty condition of the mouth with sordes on the gums The tongue became dry, glazed, covered with a thick brownish fur, and towards the crisis tended to become cracked and fissured, resembling in this respect the tongue in typhoid fever In the more ill patients it was protruded with difficulty or not at all, and showed a coarse tremor From the beginning there was loss of appetite, but great thirst was a prominent symptom throughout the entire illness In the early stages the bowels were constipated, but from the tenth to twelfth day looseness developed in several cases ("the critical evacuation") and with one patient (S B , 20 years) an acute attack of diarrhœa ensued lasting several days and followed by an intense catarrhal jaundice from the thirteenth to the twenty-third day of illness In none of the cases could either the liver or the spleen be palpated

Odour —A stale odour was detected in several of the cases, but this was not sufficiently distinctive to be regarded as specific The fœtor of the breath which was present in the cases under review was sufficient to obscure any specific odour

Nervous System —The tendency to hyperexcitability in the early stages of the disease in the younger subjects has already been referred to In the late stage of the illness there were slight meningeal features, such as an appreciable degree of nuchal rigidity and a positive Kernig's sign Hyperæsthesia was noted in some of the patients During the second week there was a loss of superficial and deep reflexes, accompanied by involuntary evacuation of bladder and bowels The pupils usually described as being contracted were not markedly so in the present series Deafness, however, was an obtrusive symptom in all but two cases All patients appeared stupid and unintelligent In the more ill patients speech became slow, slurred, and incoherent, but this seemed to be due in part to mucus collecting in the throat These cases showed a degree of mental confusion and towards the crisis exhibited a low, muttering type of delirium, talking nonsense and attempting to get out of bed, but were not unduly obstreperous Hallucinations, delusions, or unpleasant dreams did not appear to be present.

Convalescence —Convalescence was rapid and uncomplicated in all cases except for W B (10 years), who developed an urticarial eruption with a rise of temperature during the second week of convalescence, while M B (18 years) had an intractable bacilluria for ten days after her crisis Deafness and mental sluggishness disappeared in the early days of convalescence and the patients rapidly assumed their former bright appearance

Laboratory Investigations

Serological and bacteriological examination of the blood, urine, and cerebro-spinal fluid were carried out in the hospital laboratory

Blood —Blood cultures in trypsinised broth yielded negative results The red blood cells varied from 3,000,000 to 4,000,000 per c mm White blood counts showed moderate leucocytosis (15,000 to 20,000 cells per c mm), mostly polymorphonuclear in type, with a relative increase of large mononuclear and hyaline cells

Wassermann Reaction —This reaction performed before the crisis (about tenth to twelfth day of illness) was positive in four out of six cases The two negatives were J B (13 years), whose illness was of a milder nature, and Mrs McG , whose blood was tested on the sixth and eighth days of her illness The reaction, repeated in all cases (except Mrs McG , who died), on the twenty-first to twenty third days of illness (approximately a week after the crisis) was still positive in the cases of Mrs E R and S B A week later all cases gave negative results

In 1921 Bauer[2] tested the blood of 50 cases of typhus before the crisis and found that 46 of these gave a positive Wassermann reaction Tested again in convalescence 20 out of 21 gave a negative reaction, and Bauer concluded that the Wassermann reaction of typhus was almost always positive before the crisis and became negative in convalescence The findings in the present series agree with his results and support his conclusion that a positive Wassermann reaction before the crisis is helpful in the differential diagnosis between typhus and enteric fever

Weil-Felix Reaction —In carrying out this reaction the method adopted was analogous to the Widal test in typhoid A 24-hour culture of *B proteus* X 19, grown on an agar slope and emulsified in normal-saline, was used as the bacterial emulsion, and dilutions of the patients' serum were made up to 1 5000 in every case, the results being read after immersion of the tubes in the water-bath for two hours at 56° C and 20 minutes at room temperature The Weil-Felix reaction was tested with each patient's serum every day until the crisis and thereafter every second or third day until the reaction became negative The earliest day of illness on which agglutinins were demonstrated in the blood was the fifth, when a 1 25 dilution of the serum of M. B (15 years) agglutinated the *B proteus* X 19 emulsion. The serum of the other cases agglutinated the organism in a similar dilution or in 1 . 50 on the sixth and seventh days of the fever There was a rapid increase in the agglutinating power of the serum on each succeeding day until the titre for each patient's serum was reached This varied from 1 250 (Mrs E R and J B) to 1 3000 (S B and G B.), except in the case of W B , whose serum did not produce agglutination in a dilution beyond 1 50 The maximum dilution was always attained before the crisis, and was maintained for a period varying from four to seven days after the crisis, while it fell slowly to become negative at a period varying from six weeks to three months from the onset of the illness

It is, perhaps, unwise to draw conclusions from such a small series It would seem, however, that the extent to which agglutinins appeared in the blood varied directly with the severity of the case , on the other hand, the lack of reaction in the case of Mrs E R , whose illness was the most severe, would seem to be correlated to a diminished reaction of the blood in the formation of agglutinins The Weil-Felix reaction was performed with the cerebro-spinal fluid of all cases except that of G B (25 years) In only two of the cases, S B and M B (15 years), were agglutinins demonstrable In the former a dilution of 1 10 of the fluid agglutinated the proteus emulsion when the titre of the blood-serum was 1 2500, while in the latter a dilution of 1 5 of the fluid agglutinated at the time when the serum titre was 1 1000

Cerebro-spinal Fluid —In view of the results of the cerebro-spinal fluid examination of the primary case—viz., turbid fluid, increase of globulin, and a cellular exudate composed more of polymorphs than of lymphocytes and the meningeal features present in most of the cases the cerebro-spinal fluids of all the patients (except Mrs McG) were examined (*a*) in the first week of the illness, and (*b*) immediately before the crisis The fluid withdrawn at the early stage of the fever was normal in all cases, but the second lumbar puncture yielded a fluid which in the three most ill patients (M B , 15 years, S B , and Mrs E R) showed an increase of globulin (salicyl-sulphonic acid test and Pandy's test), but no cellular exudate Sugar was normal or slightly increased in amount Cultures on agar and serum were made from the centrifugalised fluid in all cases, but no growth was obtained Neither the Wassermann reaction nor the Lange colloidal gold test was performed on any of the fluids

Urine —The urines were of typically febrile type with a deposit of urates, and in the second week albumin was present in varying amounts Chlorides were diminished in quantity

Diazo Reaction —This reaction was brilliantly positive in all cases from the beginning of the fever Unfortunately a positive Diazo reaction is given with the urine of other fevers (measles, typhoid, and pneumonia) with which typhus might be confused, so that a positive result is of little diagnostic value except possibly in the early stage of the illness

Urine Cultures —Catheter specimens of the urine were taken from each of the female patients and uncontaminated specimens secured from the males on each of three successive days in an attempt to recover *B proteus* X 19 Gram-negative coliform organisms were isolated from the urine of two of the patients (M B, 15 years, and S B), but emulsions of these organisms were not agglutinated by the patients' serum Streptococci and staphylococci were present in another specimen, but these were regarded as contaminations M B (18 years) had a coliform bacilluria immediately after the crisis, although her urine had previously been sterile *B proteus* X 19 was not recovered from any of the specimens

Diagnosis

In the pre-eruptive stage of the fever there were no symptoms which could be regarded as distinctive Headache, backache, and general malaise are common to such infections as influenza, small-pox in its modified form, and typhoid fever, all of which occur in epidemic form In the present series the only features which might have helped to differentiate typhus from these diseases were the acute onset with rigors in two of the cases, and the presence within the first two or three days of positive Diazo reactions in the urines The rash, when fully developed, was distinctive of typhus The combination of papulo-macules, macules, and subcuticular lesions gave it a pleomorphic character which made it readily differentiable from the other exanthemata The dull, dusky mottled eruption of the older and more ill cases, however, might be easily missed under the conditions in which typhus is usually found The Weil-Felix reaction was not positive until the fifth day at the earliest, and usually the rash was fully developed before a positive reaction was obtained, so that its value as a diagnostic feature in the early stages of the illness was practically nil Later, however, a positive Weil-Felix reaction in a dilution of 1 50 or over might be regarded as diagnostic of typhus The Weil-Felix reaction was done in several cases of typhoid and paratyphoid fever and in scarlet fever with negative results In the later stages the fading eruption resembled closely the late stage of an intense scarlet fever rash The resemblance of the primary case to meningitis and the meningeal features present in other cases indicate the necessity for testing the blood for Weil-Felix reaction where a diagnosis of meningitis cannot be confirmed by examination of the cerebro-spinal fluid

We desire to thank Dr A S M Macgregor, medical officer of health, and Dr T Archibald, medical superintendent, Belvidere Hospital, for their helpful criticism

THE HEALTH OF THE ARMY IN 1925

THE new Blue Book [1] on the Health of the Army refers to the calendar year 1925, which, as we have already remarked, is gratifying evidence that the post-war delay is being overcome The total number of persons concerned, officers and other ranks, being almost the same as in 1924, the lessened incidence of illness is easily seen The decimal figures which follow are rates per 1000 men, the corresponding figures for the previous year being given in brackets for comparison

The officers' death-rate stood at 4 44 (3 93), that from injuries had dropped to 1 12 (1 85), while that from "diseases of the digestive system, except liver and tonsillitis" rose to 0 91 (0 39), there were more suicides among officers than among other ranks, more cases of enteric fever (2 1 against 1 1), and officers in India were found to be less well protected by inoculation (87 against 95 per cent) than other ranks This incompleteness in officers has been dealt with Amongst the 193,507 other ranks there were, in 1925, 8600 fewer cases of malaria, 3000 less in India alone, a result which may fairly be claimed as the result of foresight · there were 3600 fewer cases of influenza and a welcome reduction of 600 in the admissions for venereal disease In general there were fewer admissions, 446 2 (484 7), fewer deaths, 2 35 (2 80), fewer invalids finally discharged, 11·12 (13 00), and fewer constantly sick, 25 70 (27 11), a tangible all-round improvement The chief cause of admission was malaria, 51 8, injuries came next The chief causes of deaths were, from injuries, 0 62 (0 90), from pneumonia, 0 33 (0 33), from digestive diseases as above, 0 25 (0 21) The Commands in which the soldier had least sickness were Channel Islands, 3 9 days illness per man per annum, and Bermuda, 4 19, the heaviest incidence, 20 91 days, occurred in Malaya The 226 Woolwich cadets had a sick-list of 20 31, those at Sandhurst had 22 00, but local injuries are frequently due to training and games The boys at the Technical School, who are younger, showed a sick-list of 32 07

An outstanding feature of the year was the increase in the number of cases of gastric, 41 (25), and duodenal, 53 (29), ulcers, they cause much anxiety as they are so insidious One gastric case had no symptom prior to perforation, a man, found dead in his barrack room at 2 30 P M, had succumbed to hæmorrhage from a duodenal ulcer, and an athletic officer, admitted for severe anæmia, was similarly suffering These ulcers are apt to be associated with hyperchlorhydria and as Mr A J Walton recently reminded the Royal Society of Medicine, they attack some of the finest built men, of whom the more active and energetic tend to have hyperacidity The report calls these ulcers a disease of non-commissioned officers Their increased frequency has been noticed also in the Navy too, 52, 48, and 83 being the figures for last three available years, and was associated at a recent meeting of the War Section with recent alterations in diet These ulcers are not mentioned in the reports from India, but the death-rate there from "diseases of the digestive system, other than of liver or tonsils" has increased to 0 37 (0 24)

Fewer cases of amœbic dysentery were found in India, and fewer liver abscesses were seen, a polyvalent (Shiga and Flexner) antidysentery vaccine has been prepared Malaria is being dealt with by drainage and other antilarval engineering methods, by nets and electric fans, by better education of the individual, and by keeping troops away from the dangerous areas It seems to us doubtful whether it is wise to remit microscopical diagnosis as there seems a tendency to do from the report Pneumonia incidence is greatest at home, and its case-mortality is there highest—e g, in the Scottish (4 1, 227) and Northern (4 0, 152) Commands, the average figures at home being 2 5 and 100, the death-rate from pneumonia in India is 0 51, and in the rest of the army only 0 25 Sand-fly fever is less prevalent this year, which at Malta is thought to be the outcome of antifly measures, although the authorities at home do not expressly say so

Pulmonary tuberculosis has slightly increased 1 3 (1 2), its incidence being heaviest in Egypt (2 9), Malta, and the Rhine Venereal diseases had fewer admissions, 44 4 (46 8), particularly of syphilis, the reduction being ascribed to the increased numbers of ablution centres, through one of these, at Quetta 6057 men passed and only 8 developed disease There was great reduction in Malaya, from 108 8 to 65 2, as a result of special effort The usual treatment of syphilis is with stabilarsan and bismuth Electrical treatment of gonorrhœa has been discarded but usual treatment is more successful now than formerly, for fewer cases of stricture are met with

Encephalitis lethargica is regarded as leaving an individual "never likely to make an *efficient soldier*" One-third of the admissions for mental disease are ascribed to dementia præcox The increasing number of middle-ear complaints is causing concern A spleen was removed for splenic anæmia, and the patient is stated to be doing well An acute case of lymphatic leukæmia ended in death in 14 days Many cases of chronic appendicitis were found among cases of indefinite dyspepsia, and appendicectomy cured them In all there were 942 (881) admissions for appendicitis Some recruit depôts have had boots issued to them raised one-third of an inch on the inner side to prevent flat-foot, and care is being taken to keep the recruit off his feet as much as possible with the same object Several patients have asked for operation for internal derangement of the knee-joint to enable them to go on playing football Cases of acute synovitis of the knee are aspirated and recovery is then hastened

---

[1] H M Stationery Office Pp 152 3s 6d.

New operating rooms are being installed, and X ray coils are being replaced by high tension transformers Army cooks are given very efficient training, and the Inspector of Army Catering does much to improve the dietary of the soldier Recruits from country districts have the better teeth, only 4 8 per man diseased or missing, but 6 7 in those from industrial areas, though these have the cleaner mouths, the best and worst were in Scotland (1 4 and 9 3) On the average 4 34 (4 18) diseased teeth were dealt with per man, and Indian troops began to be helped

There were 381 more recruits examined this year; fewer were rejected and fewer discharged under six months' service Diseases of the middle ear caused most of the rejections in both groups There were fewer rejections for insufficient weight, deficient height or chest measurement It may be that we are now getting past the nutritional handicap of the war The sanitary education spreading from the Army School of Hygiene, which dealt with 121 officers and 1263 other ranks in the year, is thought to have assisted in securing the improvement observed in the sanitary condition of camps A very striking improvement was noted in the health of troops on board ship, admissions being 184 0, instead of 233 0, and no deaths, this may be associated with the increased cubic space and better ventilation

MEDICINE AND THE LAW.

"ADEQUATE MEDICAL AID" · THE PARENT'S LEGAL DUTY

CAN a parent refuse to have his children's teeth extracted for the benefit of their health? Can he decline to allow their adenoids or tonsils to be removed? The answer to these questions was given in the negative nearly 20 years ago, but there are fathers and mothers who are still unaware of their legal responsibility Section 12 of the Children Act made it an offence for a parent or guardian to ill-treat a child The offence was made to cover any wilful neglect which caused the child unnecessary suffering or injury to health, it also covered the omission to provide adequate medical aid Nor was this latter responsibility confined only to those wealthier parents who could afford to pay for the services of doctor and surgeon; it was laid equally upon the less well-to-do who are liable to punishment if they fail to take advantage of the medical services which in various ways are provided for children without charge Thus a fortnight ago a father and mother were summoned at Tower Bridge Police-court for neglecting to have dental treatment for their son, aged 10 The prosecution said that representations had been made to the parents for the last five years about the boy's teeth and that free treatment had been offered and refused It was said that in consequence the boy had suffered from abscesses in the jaw, anæmia, carious teeth, and enlarged glands, and that his health was generally poor His father admitted that the boy's teeth were bad, but said that his son had been attended by a private dentist and that the London County Council doctors wanted to take all the lad's teeth out at once The magistrate fined the father 40*s* and 3 guineas costs and fined the mother 20*s* This was a more vigorous sentence than that of the Bridlington judges, who had recently to deal with another charge under Section 12 The summons was for omitting to have a daughter's tonsils removed, the child having been caused unnecessary suffering and injury to health because the operation had not been performed Dr. A K Jarratt, school medical officer and medical officer of health for the borough of Bridlington, gave evidence that the little girl's tonsils were so greatly enlarged that they almost met, he said it was the worst case he had seen in the schools in 16 years of attendance; he pointed out the danger to the child if she should suffer from an affection of the throat, pneumonia, scarlet fever, or diphtheria He had many times advised the parents, the nurse had also tried to persuade them to have the operation performed, but they would not consent Dr James Kirk gave similar evidence, and no rebutting evidence was called for the defence All that the father and mother could say was that the little girl never ailed; she was good at her lessons and well up in her class; why should she have an operation when there was nothing wrong with her? The father said there was a similar case in the same street where a little girl had had her tonsils taken out and was none the better for it, if his daughter had to go to hospital she would cry all the time she was there The magistrates asked the doctors several questions as to the possible risk of the operation, they were evidently reluctant to interfere with the liberty of the subject, yet the medical evidence was clear that the child's growth and development were being impeded and her powers of resisting illness diminished Finally the bench compromised by adjourning the proceedings and giving the parents a month's grace in which to comply with the medical requirements If the magistrates had been aware of the facts and the judgments in the leading case on the subject (Oakey *v.* Jackson, decided in 1914) they might have taken a stronger line

Oakey *v* Jackson was a case in which a little girl suffered from adenoids and her parents refused to have an operation There was medical evidence that the disability was causing mental dullness, impaired breathing, deafness, and anæmia, and that a surgical operation for removing the adenoids was the only remedy The parents did not consider an operation necessary, and did not believe in operations at all —though, apart from this refusal, there was no evidence of neglect It was argued on their behalf that the Children Act was never intended to compel surgical operations involving the administration of anæsthetics and, perhaps, involving an element of danger to life Accepting this view the Leicestershire magistrates, before whom the parents were brought, held that there was no legal liability to allow the operation to be performed and that refusal was not wilful neglect within the meaning of the Act In the King's Bench Division, Darling, J, said that the words of the Act referring to injury to or loss of sight quite clearly showed that the statute contemplated cases of compelling a parent to allow a child to undergo an operation "It is not necessary to know much about surgery," said the learned judge, "to know that the operation for the removal of adenoids is very common in the case of children and that a failure to perform the operation may result in danger to the child's life if the child should ever happen to be attacked with illness" The judges held that whether or not there had been a failure to provide adequate medical aid must depend on the facts of each particular case They thought the magistrates might very well have convicted the parents on the facts stated, and they sent the case back to the magistrates for further consideration Mr Justice Avory added that one matter to be taken into consideration by the justices in deciding cases of this kind was whether the person who advised the operation was a qualified medical practitioner or merely some irresponsible person As for "wilful neglect," the judges approved the dicta of Lord Russell of Killowen when Lord Chief Justice In a case decided in 1899 he said that "wilful" meant that the act was done deliberately and intentionally, not being accident or inadvertence, but so that the mind of the person who did the act went with it "Neglect" meant want of reasonable care, the omission of such steps as a reasonable parent would take, such steps as are usually taken in the ordinary experience of mankind, provided that the parent had such means as would enable him to do what was necessary Means, we know, are forthcoming for the free treatment of school-children in necessitous cases Parents are often reluctant to send their children to hospital, and magistrates are equally reluctant to use legal compulsion where persuasion has failed But it is well that there should be no doubt that the parents have, in fact, a legal responsibility and that they commit an offence if they obstruct the provision of adequate medical and surgical aid, and thus fail to give their children the best possible chance in life

THERAPEUTIC SUBSTANCES ACT, 1925

DRAFT RULES AND ORDERS

IN August, 1925, an Act was passed designed to secure the potency and purity of those therapeutic substances in the market for which standards and methods of testing have been devised, but which cannot be tested by purely chemical means These substances at present include (1) vaccines, toxins, antigens, sera, and antitoxins, (2) salvarsan and its derivatives, (3) insulin and pituitary extract A joint committee of the licensing authorities concerned in the Act was formed, these authorities being, for England, the Minister of Health, for Scotland, the Secretary of State for Scotland, and for Northern Ireland, the Minister for Home Affairs To assist this joint committee in devising standards and drawing up regulations an advisory committee was set up, consisting of the following personnel Sir George Newman (Chairman), representing the Ministry of Health, Mr John Jeffrey, the Scottish Board of Health, Sir Thomas Houston, the Ministry of Home Affairs in Northern Ireland, Dr H H Dale, F R S, the Medical Research Council; Sir Nestor Tirard, the General Medical Council, Dr C O Hawthorne, the British Medical Association, Dr J H Burn, the Pharmaceutical Society of Great Britain; and Dr J F Tocher, the Institute of Chemistry

The result of the labours of these committees has now been published in the form of the draft regulations,[1] summarised below, which are to come into operation on August 6th, 1927

The Proposed Regulations

The regulations consist of seven parts supplemented by forms of application for licence and detailed schedules of the specific requirements for each substance The first part is concerned with definitions, the second with licences for manufacture of therapeutic substances Each licensee will have to provide and maintain adequate staff, premises, and plant, not only for the proper manufacture of the substance in respect of which the licence is issued, but also for carrying out tests of strength, quality, and purity, unless he makes arrangements with some approved institution for tests to be carried out regularly on his behalf He must keep records of the details of manufacture of each batch of the substance, and of the application of the tests, in a form convenient for inspection Any premises where manufacture of therapeutic substances is carried on are to be liable to inspection, also the processes of manufacture and the means employed for standardisation and testing Any change in the expert staff responsible for manufacture or testing of the substances used, or any material alterations in the premises or plant have to be notified The continued production of any substances under conditions which do not satisfy the licensing authority will not be allowed

The third part of the regulations provides for the proper labelling of the containers in which the substances are sold If any therapeutic substance is advertised or sold as a proprietary medicine or is contained in medicine so advertised or sold, the name stated in the relative schedule as being the accepted scientific name or name descriptive of the true nature and origin of the substance is to appear on the label Moreover, the proper name of the substance is to be set out in letters not smaller or less conspicuous than those in which the proprietary name, if any, is printed or written On the label, or printed or written in indelible ink on a wrapper, is to be set out the name and address of the manufacturer, the number of the licence under which the substance is manufactured, a distinctive batch number, the date on which the manufacture of the batch was completed, and a statement of potency or toxicity where tests for potency or toxicity are required

An interesting provision is that—

> No person shall sell any therapeutic substance after the date recorded on the container, label, or wrapper as the date up to which the substance may be expected to retain a potency not less than, *or not to acquire a toxicity greater* than, that required or permitted by the test, as the case may be Provided that a person may at the request of a registered medical practitioner sell after the date aforesaid any therapeutic substance (except such as are required to be tested for maximum toxicity) which loses its potency, if he has previously drawn the practitioner's attention to the dates recorded on the container, label, or wrapper, and the practitioner is satisfied that the sale is required by the urgency of the case

The fourth part of the regulations deals with standards of strength, quality, and purity and tests for determining whether these standards have been attained Precautions are taken to ensure that the preparations are sterile and that the samples are typical of the rest of the batch The hydrogen-ion concentration of the media to be used in making the tests is set out, and a general account is given of the methods used.

In Part V of the regulations licences for import of therapeutic substances are considered, precautions being taken to see that substances not manufactured in this country but offered for sale here should not fall below a reasonable standard

Research Licences.

In Part VI the conditions on which special licences to import therapeutic substances for the purpose of scientific research are to be granted are set out as follows —

> (1) The licensee shall use the substances imported under the licence for purposes of scientific research exclusively, and shall carry on such research in the place specified in the licence,
>
> (2) The licensee shall allow any inspector authorised by the licensing authority in that behalf to enter with or without prior notice the premises where the substances are kept and to inspect the premises and investigate the manner in which the substances are being used, and to take samples thereof,
>
> (3) The licensee shall keep a record of the substances imported under the licence, together with the quantities imported, the date of importation, and the name of the manufacturer,
>
> (4) The licensee shall comply with such further requirements, if any, applicable to the holders of research licences, as may be specified in any regulations which may be made under the Act, and of which the licensing authority has given to the licensee not less than one month's notice

Part VII provides that the regulations are not applicable to therapeutic substances which are labelled as intended to be used only for veterinary purposes

Schedules

The schedules which follow the draft regulations include forms of application for various forms of licence and the provisions applicable respectively to the production of bacterial vaccines, of vaccine lymph, of toxins and antigens, of diphtheria prophylactic, of tuberculin and tubercle vaccines and of sera from living animals The provisions as to particular sera and antitoxins are then set out, including those applicable to antimeningococcus serum and to other sera for which no potency test is described, to anti-dysentery sera, to diphtheria antitoxin, and to tetanus antitoxin The third schedule gives details of the general provisions applicable to salvarsan and its derivatives and the special provisions applicable to various named derivatives The fourth schedule is concerned with insulin It is to be a condition of every licence for the manufacture of insulin that it shall be issued either as a sterile watery solution or in the form of sterile compressed tablets readily and completely soluble in water, that insulin shall not be issued mixed with other therapeutic agents except with the previous consent of the licensing authority, and that insulin shall not be issued with the recommendation for its administration by any other method than that by injection through the skin The schedule concerned with pituitary (posterior lobe) extract concludes the list

---

[1] Draft Rules and Orders 1927 Therapeutic Substances H M Stationery Office Pp 33 9d

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

Infectious Disease at Dairies

THIS is the title of a compact circular just issued by the Scottish Board of Health The object of the circular is to point out what the dairymen and their employees can do, and may be punished for not doing, in their efforts to assist the local health authority to protect the milk-supply from contamination with infectious diseases In this regard the Milk and Dairies (Scotland) Act, 1914, which, after one or two postponements on account of the war or post-war conditions, is now in force, placed on dairymen and their workers very specific obligations It is the manifest interest of dairymen to take every step at the earliest moment to secure that no infected person handles cows or milk, and to invoke the help of the medical officer of health It appears to be the case, however, that, according to the circular, " when a milk-supply is suspected of causing disease the attitude of the producer of milk and his employees is too often one of indifference or of actual obstruction " These, as every county or city medical officer knows, are very mild words for the conditions experienced Fortunately, the machinery for detection is now efficient enough to create a wholesome fear, and fear is a good schoolmaster even for slow wits

The circular details with precision the legal duties of dairymen and their employees and the powers of the medical officer of health and the local authority To give special point to the new circular, the Board records the following —

> " During 1926 several outbreaks of infectious disease were spread by milkers who, themselves infected, continued to milk cows In one outbreak about 150 cases of dysentery were caused by a milker who had contracted the disease and continued at work, though she suffered from what was apparently diarrhœa, and broke the law by continuing to work while so suffering In another outbreak over 150 cases of scarlet fever were caused by a milkmaid who continued to milk cows while suffering from a mild attack of scarlet fever In spite of careful inquiries, essential facts were withheld from the medical officer of health which, had they been disclosed, would almost certainly have curtailed this serious outbreak "

The circular is to be had from the Stationery Office for 1*d*, and all concerned should possess it

Sampling of Bottled Milk

In response to representations by the Association of Public Analysts the Scottish Board of Health has issued a short set of directions for sampling bottled milk under the Sale of Food and Drugs Act At first sight nothing seems more simple But experience tells a different tale, for we learn that " unequal distribution of the butter-fat is particularly liable to occur in the case of bottled milk, and as the sale of bottled milk is spreading rapidly, it is necessary to reconsider the methods of official sampling " The point is to secure that, before the sample is taken, the milk shall be thoroughly mixed Evidence laid before the recent Scottish Departmental Committee on the Milk Standard showed how many pitfalls there are in sampling even when the persons concerned are all honest Case after case has been wrongly decided on account of slip-shod sampling This circular contains a series of nine special precautions and these have obviously been carefully thought out in concert with analysts and sampling officers This circular also is to be had for 1*d* and should be in general circulation

Physical Education

The College of Hygiene and Physical Education at Dunfermline continues to be the centre of Scottish activities in physical education and related subjects It is many years ago since, in cooperation with the Scottish Education Department and its officers, the Dunfermline Carnegie Trustees converted the College into a type of medical school, with a medical principal and medical teachers, and trained lay specialists in modern methods of physical education and remedial gymnastics The College is now a " central institution " under the code Last week a four days' special course ended, having been attended by 135 students and teachers from all parts of England, Scotland, and Ireland The course, which included lectures and demonstrations in respect of physical education swimming, gymnastics, dancing, and games (including umpiring), was conducted under the auspices of the Scottish League for Physical Education (Women), the Carnegie Trustees granting the use of the College and gymnasium for lectures and demonstrations

How eminently fitted for these purposes this carefully designed College is, only those familiar with its past work can understand Andrew Carnegie placed Scotland in an enviable position when he made this fine institution possible

The Reorganisation of Offices (Scotland) Bill.

The Bill for the conversion of the Scottish Board of Health and the Scottish Board of Agriculture from " boards " into " departments " of health and agriculture respectively, has not yet passed the second reading, the debate having been adjourned under the rules of the House Meanwhile, the Executive Committee of the National Farmers' Union of Scotland have had the matter before them and have passed a unanimous resolution protesting " against this Bill in so far as it proposes to abolish the Board of Agriculture in Edinburgh " It is interesting to find that, at last, the farmers have something good to say about the Scottish Board of Agriculture, but the importance of their resolution lies chiefly in the fact that this Board and the Board of Health stand or fall together The resolution, however, stresses the wrong point In his second reading speech, Sir John Gilmour made it perfectly clear that, so far as the relation of London to Edinburgh was concerned, the Bill made no difference whatever At the present moment the Secretary of State for Scotland is head of both Boards and controls, positively and negatively, everything they do The Boards are not independent in any sense For each of them the Secretary of State is responsible and neither board is final in any decision Sir John Gilmour pointed out that the day for the " board " type of executive was over and the " department " type, as in the Scottish Education Department and the Ministry of Health was, at least for these two boards, preferable There is much to be said for and against, but when the change is made the relationship to London will remain as it is now The history of all the Scottish " boards " is long and interesting It would form a good study in the working of political patronage This, indeed, was one of the points urged in favour of the reform

CHEMICAL RESEARCH AT NOTTINGHAM —It is announced that Boots Pure Drug Company, Ltd, have decided to extend the scope of their research work at Nottingham, new laboratories are being equipped and the staff of research chemists will be increased The head of the research laboratories will be Mr F L Pyman, D Sc, F R S, professor of technological chemistry in the University of Manchester and in the College of Technology He is well known for investigations into the chemistry of the alkaloids and of related synthetic compounds, recently he has devoted much attention to the glyoxaline group and has effected a synthesis of histidine

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

County Borough of Plymouth.

1926 statistics: population—211 350: birth-rate. 17·2; death-rates per 1000 of the population: all causes. 12·3: tuberculosis 1·0: cancer. 1·5: respiratory diseases with influenza. 2·6: heart disease 1·5 Death-rates per 1000 births: neonatal. 2·9: infant. 72: mothers from childbirth. 3·0.

Dr. A. T Nankivell in last year's report said he would like to see every medical member of his staff engaged in some research work and, following up this idea, he writes the introduction to this year's report and leaves it to his staff to deal in special reports with various aspects of the public health work in Plymouth and its institutions The cost of the maternity and child welfare work is less than a penny rate An additional woman doctor and two more health visitors have been appointed; ultra-violet light has been installed at Stonehouse and a new centre approved at Beaumont Park. Dr Ann Clark reports that antenatal clinics have been increased from one to four per week and that the antenatal work of the nursing associations is now conducted by her staff. She also reports in detail as to the results of light treatment which has been chiefly beneficial in rickets but cases of malnutrition chronic bronchitis anæmia, and skin disease have also responded well To achieve the aim that no confinements shall take place in squalid and dirty homes, a long and difficult fight is needed, says Dr Nankivell, in order to overcome the west country prejudice which exists against lying-in homes and in favour of mothers being confined in their own tenements, however unsuitable these may be Plymouth also needs a convalescent home for debilitated mothers a hostel where little children may be cared for when the mother is in hospital or sanatorium, and day nurseries

The school service needs a residential open-air school in the country, an increase in the dental staff and a third dental clinic During the last three years the Wassermann test was recommended for 307 children In 26 cases the parents refused In 72 a positive result was obtained: 34 of these children being at ordinary schools, 22 at mental deficiency schools 14 at open-air schools, one at a school for the deaf, and one not at school. Dr. G. D. Kettlewell, the V.D. officer, says it has always been recognised that a large number of congenital syphilitics were not being treated in Plymouth Special efforts have been made in recent years to search them out, and a table is given showing the nature of the 533 cases which have been treated at the centre since 1919 Of these 313 were children of school age and included 66 cases of serious eye trouble mostly due to ulceration: 7 deaf children: 23 sufferers from bone disease, of whom 10 were cripples and 2 had been absent from school for over two years owing to the offensive smell from the nose: 15 cases of skin disease: and 71 mentally deficient (of whom nearly all have improved greatly under treatment). Thirty-three of the brothers and sisters who themselves showed no signs' were treated tentatively and the majority improved generally in health and development Physically all congenital children are stunted," says the report. ill-developed, and diminutive, many of 10 and 12 years are physically aged 6.' The estimate is put forward that there are 1000 congenital syphilitics among the children in Plymouth needing treatment including the 313 already receiving it. School teachers and nurses have given the very greatest help in searching out these children Dr. Kettlewell points out the handicap for life of these subjects many being quite unable to earn a living while many will live in institutions for the blind and mentally defective, tragedies some of which might have been averted if the children had been treated early enough.

Plymouth has now obtained hospital accommodation on shore for small-pox at the Lee Mill Hospital of the Plympton rural district council and it is intended to add 20 beds to this hospital; the port medical officer, Dr Arthur Massey, points out that Plymouth is specially exposed to risk through its shipping and that the hospital ship *Flamingo* was quite unfitted to fulfil the function of providing accommodation for small-pox. One case was landed from shipboard during the year without spread.

The damage done by rats in Plymouth is estimated at £300 000 annually. Energetic warfare is waged against them all the year round and not only in a ' rat week. Dr Massey urges, however, that much could be done by naval architects to reduce ' rodent amenities' to a minimum, when the ships are constructed. The experiment was tried of spraying the sea gulls with a special methylene-blue solution to find out if they went from the sewage outfalls to the fresh water reservoirs No blue gulls were afterwards seen around reservoirs or docks—a fact which has not been satisfactorily explained' Sir Alexander Houston's contention, it may be remembered, is that at some of the Metropolitan Water Board reservoirs frequented by gulls, the tendency for the *B. coli* to be reduced by storage of the water may be more than counteracted by the number of *B coli* in the excreta of the gulls dropped into the water.

The tuberculosis death-rate as shown by a chart, remained stationary during 1920–24, but showed a distinct decline in both 1925 and 1926 More hospital and sanatorium accommodation is needed for both pulmonary and non-pulmonary cases, as there is always a distressing waiting-list. The shortage of low-rented houses remains acute. Sooner or later, says Dr Nankivell we shall have to recognise that subsidised houses for persons who can only pay 2*s* 6*d*. a week rent are needed in every town He would also like to see municipal hostels or common lodging-houses provided, one for men, one for women, and one for married coulpes

Three insanitary areas were scheduled more than a year ago but progress is very slow. The renovation of houses, however, continues to be satisfactory and owners spent about £28 000 in repairing old property during 1926 Over 800 samples of milk were examined bacteriologically and as the vendors are always informed of adverse findings this helps to improve the cleanliness of the milk-supply. About 700 churns come in daily, and Dr. Nankivell would like to have the contents of each churn examined once a month instead of once a year, as at present. The demand for clean milk grows: 33 dairymen sell ' Certified or Grade A milk. The M and C W. centres obtain ' Certified, the isolation hospital Grade A (t t)' and the relief milk for consumptives is "Grade A."

Health propagandism has included many lectures by the medical staff, the issue of a booklet ' Health Hints —to the extent of 55 000 copies a free health film week, leaflets and posters and much help from the press

---

REPORTS OF PORT MEDICAL OFFICERS.

The Tyne.

IN his report for 1926 to the Tyne Port Sanitary Authority Dr. W. E Harker states that he visited 56 vessels on account of sickness reported or suspected on board, and removed from ships one case of influenza, one of diphtheria, and one of enteric fever No infectious disease was found among the 9414 alien passengers who were mostly clean. No case of cholera, plague or yellow fever came under notice, but 3171 rats were caught on 78 vessels On 15 ships a total of 229 rats were killed with sulphur dioxide; hydrocyanic acid was not employed Just over half the dead rats were black and none of them was infected with plague. Seventeen ships had their drinking-water tanks emptied and purified because they came from ports at which cholera was present or suspected.

The main food imports into the Tyne were wheat, sugar, eggs, and fruit; no condemnations are reported. The fish landed was good; 28 of 7921 fishing boats derivatives and the special provisions applicable to various named derivatives The fourth schedule is concerned with insulin It is to be a condition of every licence for the manufacture of insulin that it shall be issued either as a sterile watery solution or in the form of sterile compressed tablets readily and completely soluble in water, that insulin shall not be issued mixed with other therapeutic agents except with the previous consent of the licensing authority, and that insulin shall not be issued with the recommendation for its administration by any other method than that by injection through the skin The schedule concerned with pituitary (posterior lobe) extract concludes the list

SCOTLAND.

(FROM OUR OWN CORRESPONDENT)

Infectious Disease at Dairies

THIS is the title of a compact circular just issued by the Scottish Board of Health The object of the circular is to point out what the dairymen and their employees can do, and may be punished for not doing, in their efforts to assist the local health authority to protect the milk-supply from contamination with infectious diseases In this regard the Milk and Dairies (Scotland) Act, 1914, which, after one or two postponements on account of the war or post-war conditions, is now in force, placed on dairymen and their workers very specific obligations It is the manifest interest of dairymen to take every step at the earliest moment to secure that no infected person handles cows or milk, and to invoke the help of the medical officer of health It appears to be the case, however, that, according to the circular, "when a milk-supply is suspected of causing disease the attitude of the producer of milk and his employees is too often one of indifference or of actual obstruction" These, as every county or city medical officer knows, are very mild words for the conditions experienced Fortunately, the machinery for detection is now efficient enough to create a wholesome fear, and fear is a good schoolmaster even for slow wits

The circular details with precision the legal duties of dairymen and their employees and the powers of the medical officer of health and the local authority To give special point to the new circular, the Board records the following —

> "During 1926 several outbreaks of infectious disease were spread by milkers who, themselves infected, continued to milk cows In one outbreak about 150 cases of dysentery were caused by a milker who had contracted the disease and continued at work, though she suffered from what was apparently diarrhœa, and broke the law by continuing to work while so suffering In another outbreak over 150 cases of scarlet fever were caused by a milkmaid who continued to milk cows while suffering from a mild attack of scarlet fever In spite of careful inquiries, essential facts were withheld from the medical officer of health which, had they been disclosed, would almost certainly have curtailed this serious outbreak"

The circular is to be had from the Stationery Office for 1*d*, and all concerned should possess it

Sampling of Bottled Milk

In response to representations by the Association of Public Analysts the Scottish Board of Health has issued a short set of directions for sampling bottled milk under the Sale of Food and Drugs Act At first sight nothing seems more simple But experience tells a different tale, for we learn that "unequal distribution of the butter-fat is particularly liable to occur in the case of bottled milk, and as the sale of bottled milk is spreading rapidly, it is necessary to reconsider the methods of official sampling" The point is to secure that before the sample is taken, the milk shall be thoroughly mixed Evidence laid before the recent Scottish Departmental Committee on the Milk Standard showed how many pitfalls there are in sampling even when the persons concerned are all honest Case after case has been wrongly decided on account of slip-shod sampling This circular contains a series of nine special precautions and these have obviously been carefully thought out in concert with analysts and sampling officers This circular also is to be had for 1*d* and should be in general circulation

Physical Education

The College of Hygiene and Physical Education at Dunfermline continues to be the centre of Scottish activities in physical education and related subjects It is many years ago since, in cooperation with the Scottish Education Department and its officers, the Dunfermline Carnegie Trustees converted the College into a type of medical school, with a medical principal and medical teachers, and trained lay specialists in modern methods of physical education and remedial gymnastics The College is now a "central institution" under the code Last week a four days' special course ended, having been attended by 135 students and teachers from all parts of England, Scotland, and Ireland. The course, which included lectures and demonstrations in respect of physical education swimming, gymnastics, dancing, and games (including umpiring), was conducted under the auspices of the Scottish League for Physical Education (Women), the Carnegie Trustees granting the use of the College and gymnasium for lectures and demonstrations

How eminently fitted for these purposes this carefully designed College is, only those familiar with its past work can understand Andrew Carnegie placed Scotland in an enviable position when he made this fine institution possible

The Reorganisation of Offices (Scotland) Bill

The Bill for the conversion of the Scottish Board of Health and the Scottish Board of Agriculture from "boards" into "departments" of health and agriculture respectively, has not yet passed the second reading, the debate having been adjourned under the rules of the House Meanwhile, the Executive Committee of the National Farmers' Union of Scotland have had the matter before them and have passed a unanimous resolution protesting "against this Bill in so far as it proposes to abolish the Board of Agriculture in Edinburgh" It is interesting to find that, at last, the farmers have something good to say about the Scottish Board of Agriculture, but the importance of their resolution lies chiefly in the fact that this Board and the Board of Health stand or fall together The resolution, however, stresses the wrong point In his second reading speech, Sir John Gilmour made it perfectly clear that, so far as the relation of London to Edinburgh was concerned, the Bill made no difference whatever At the present moment the Secretary of State for Scotland is head of both Boards and controls, positively and negatively, everything they do The Boards are not independent in any sense For each of them the Secretary of State is responsible and neither board is final in any decision Sir John Gilmour pointed out that the day for the "board" type of executive was over and the "department" type as in the Scottish Education Department and the Ministry of Health was, at least for these two boards, preferable There is much to be said for and against, but when the change is made the relationship to London will remain as it is now The history of all the Scottish "boards" is long and interesting It would form a good study in the working of political patronage This, indeed, was one of the points urged in favour of the reform

Health propagandism has included many lectures by the medical staff, the issue of a booklet " Health Hints "—to the extent of 55,000 copies a free health film week, leaflets and posters, and much help from the press

---

REPORTS OF PORT MEDICAL OFFICERS

The Tyne

IN his report for 1926 to the Tyne Port Sanitary Authority Dr W. E Harker states that he visited 56 vessels on account of sickness reported or suspected on board and removed from ships one case of influenza, one of diphtheria and one of enteric fever No infectious disease was found among the 9414 alien passengers, who were mostly clean No case of cholera, plague or yellow fever came under notice but 3171 rats were caught on 78 vessels On 15 ships a total of 229 rats were killed with sulphur dioxide , hydrocyanic acid was not employed Just over half the dead rats were black and none of them was infected with plague Seventeen ships had their drinking-water tanks emptied and purified because they came from ports at which cholera was present or suspected.

The main food imports into the Tyne were wheat, sugar, eggs, and fruit , no condemnations are reported. The fish landed was good ; 28 of 7921 fishing boats had to be cleansed and deodorised In 6538 inspections of ships sanitary defects were found in 11 per cent of foreign-going and in 6 per cent of coasting vessels Peaks, fo'c'sles, w c 's, and bilges of 541 vessels were found dirty and were cleansed, 1016 old beds were burned on account of infection. Many structural defects were noted and rectified The 18 water boats of the port were examined and their tanks found in good condition

The Tyne Floating Hospital is now reserved for the isolation and treatment of the more dangerous infections from overseas, and is also equipped as a cleansing station Other infectious cases are sent to the City Hospital The usual measures were taken for the treatment of venereal disease, but Dr Harker offers no estimate of their usefulness

The work of the port decreased during 1926 by 20 or 30 per cent, probably because of the coal dispute

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 9TH, 1927

Notifications —The following cases of infectious disease were notified *during the week* —*Small-pox*, 391 (last week 392), scarlet fever, 1271, diphtheria, 943, enteric fever, 40, pneumonia, 1052, puerperal fever, 32, puerperal pyrexia, 101, cerebro-spinal fever, 10, acute poliomyelitis, 7, encephalitis lethargica, 30, continued fever, 2, dysentery, 6, ophthalmia neonatorum, 132 No case of cholera, plague, or typhus fever was notified during the week No further cases of small-pox were notified in Kent or Surrey.

Deaths —In the aggregate of great towns, including London, there was no death from small-pox, 2 (0) from enteric fever 76 (5) from measles, 2 (0) from scarlet fever, 76 (19) from whooping-cough, 28 (9) from diphtheria, 37 (6) from diarrhœa and enteritis under two years, and 120 (14) from influenza The figures in parentheses are those for London itself

---

The 1921 Census —The General Report on the Census of England and Wales, 1921, published on April 19th (H M Stationery Office 5*s*) completes the series of official volumes issued in respect of the 1921 Census, dealing with the country as a whole in much the same way as the report issued with each county volume dealt with the local figures The first and most important section deals with the numbers of the population its distribution throughout the country, its growth since the preceding census in comparison with that of earlier periods, and also with the contemporaneous growth of other nations The population numbered rather more than 37¾ millions, 649 to each square mile on the average, or about an acre per head, a density greater than that of any country in the world for which statistics are available Nearly 80 per cent of the population were enumerated as living in urban areas, and of these practically half were found in comparatively dense aggregates represented by 46 towns each containing more than 100,000 persons The rate of growth of the smallest towns is above the average for the whole country, and the rate appears to increase as the towns get larger, until the populations reach a figure in the neighbourhood of 100,000 After this the rate of increase tends to slacken off, suggesting that 100,000 roughly marks a limit of effective aggregation beyond which the advantage of further accretion begins to be offset by counterbalancing disadvantages Prominent amongst the towns which showed little increase or which decreased during the decennium are those associated with the textile industry in Lancashire and Yorkshire The new section on Dependency and Orphanhood provides a survey of the sizes, age constitution and distribution of economically dependent families in relation to their parents The comparative rarity of the large family in general is exemplified by the average which for all married men taken together measured only 1 27 children apiece More than 13 per cent of the married men returned no children under 16, while in another 23 per cent there was one child only Miners returned the largest families on the whole, but even so their average was only 1 82 for each married man, while in the case of professional men the figure sinks as low as 0 90 The fertility study, derived indirectly from the dependency statistics, throws light upon certain aspects of the birth-rate in this country which is not obtainable from the ordinary registration records

Correspondence.

"Audi alteram partem"

TESTS FOR DRUNKENNESS

To the Editor of The Lancet

Sir,—The British Medical Association Committee, under the able and wise guidance of its Chairman, Major-General Sir William Macpherson, gave the fullest attention to all possible methods for determining whether "a person concerned was so much under the influence of alcohol as to have lost control of his faculties to such an extent as to render him unable to execute safely the occupation in which he was engaged at the material time" The evidence put before the Committee proved conclusively —

(1) That in different individuals the quantity of alcohol required to impair the function of the higher nerve centres was subject to great variations—e g, in a person unaccustomed to alcoholic consumption a very slight amount might cause serious impairment, while in the case of the person inured to the effects of alcohol relatively large amounts might be ingested without appreciable impairment of control of the faculties

(2) That in the performance of complex occupational acts such as the driving of a motor-car an experienced driver might be little affected by relatively large amounts of alcohol since his long experience of driving has caused his control of the car to become almost automatic.

On the other hand, a driver of less experience who has to think of each of the special actions required for the complete control of his car before their execution would be seriously affected by a relatively small amount in his driving efficiency, whereas as regards other occupations to which he had long been accustomed his faculty control might be perfect It was considerations such as these which caused the Committee to refrain from placing definite limits on the percentage of alcohol in the blood, cerebro-spinal fluid, or urine which would serve as absolute indications of drunkenness

The Committee attached the highest importance to the valuable work of Dr Southgate on the excretion of alcohol in the urine and its presence in the blood, and each member of the Committee was provided with a copy of his paper I myself presided at the meeting of the Medico-Legal Society at which Dr Southgate and Dr Godfrey Carter read their paper On the Excretion of Alcohol in the Urine as a Guide to Alcoholic Intoxication, and at that meeting I described this work as a most important and valuable contribution to the science of toxicology. In the present state of our knowledge, however, it is impossible to give exact figures of the percentage of alcohol in blood or urine, which would in any individual mean that the borderland of sobriety had been passed, and the authors of the paper refrained from giving such an exact figure

Apart from this difficulty there were definite legal objections to the application of the test by the prosecuting authority—for example, the taking of a sample of blood from an accused person who was unwilling might be technically regarded as a legal assault *There is no objection to the application* of the test provided that the accused person is willing, and it is to be hoped that this test will be used with increased frequency, and so lead to an extension of our knowledge in the diagnosis of drunkenness I can imagine no better defence for an accused person than the evidence that the blood and urine at the time of arrest were free from alcohol

The diagnosis of drunkenness is attended with great difficulty, and the Committee stated that no single test by itself would, as a rule, justify a decision one way or the other Dr Southgate is under a misapprehension when he suggests that the Committee regarded the smell of alcohol as a test for drunkenness A careful perusal of the report will show that all that was claimed for the olfactory test was that "the smell of alcoholic liquor in the breath or in vomited matter (if any) is a sign of the consumption of alcohol," and conversely that the absence of any smell of alcoholic liquor in the breath of a person at the time of arrest renders it improbable that he had recently consumed alcohol.

The decision as to drunkenness would not rest on this test at all, but on the other tests enumerated in the report.—I am, Sir, yours faithfully,

W. H. WILLCOX.

Welbeck-street, Cavendish-square, W., April 13th, 1927.

VENESECTION FOR NARCOTIC POISONING

To the Editor of THE LANCET

SIR,—Your report of the discussion at the Royal Society of Medicine on venesection recalls to my mind an occasion when a free venesection saved the life of a lady who appeared to be dying from the effects of laudanum poisoning.

The patient had swallowed some six ounces of laudanum at least half an hour before I saw her. At first, owing to wild excitement, it was impossible to control her in any way, but she rapidly passed into a stupor, and then her stomach was washed out. Stupor quickly deepened into coma with stertorous breathing, deep cyanosis, and commencing œdema of the lungs. At this stage a free venesection was performed and the beneficial effect was soon apparent. A few hours later the patient was well on the way to recovery. Readers of De Quincey will remember his assertion that opium, in whatever quantity it is taken, does not produce *intoxication*, and that any symptoms of this nature are due to the proof spirit with which the laudanum is prepared. The preliminary stage of wild excitement recorded above may have been induced in this way.

The treatment of opium poisoning by flagellation, cold douches, and exercise forced to the point of exhaustion is now a thing of the past. Since my early hospital days improvements on the treatment then in vogue have taken the form of washing out the stomach with permanganate solutions and, due I believe to a communication by Sir William Hale-White, the use of oxygen inhalation. My experience, given above, leads me to urge also the use of free bleeding when coma is accompanied by cyanosis and signs of respiratory failure.

On leaving the patient's ground-floor flat after several anxious hours, the surgeon and myself were stopped by a constable on the doorstep and requested to give an account of our actions. We had been watched for some time through a crack in the blind!

I am, Sir, yours faithfully,

CHARLES R. BOX.

Devonshire-place, W., April 18th, 1927.

IODISM WITH GLOTTIS ŒDEMA

To the Editor of THE LANCET

SIR,—In regard to the occurrence of glottis œdema in subjects with an idiosyncrasy towards iodides, as in the case recorded by Drs. N. W. Snell and L. H. Savin (THE LANCET, April 9th, p. 759), it would be worth while in a similar case to try whether the necessity for tracheotomy could be avoided by a subcutaneous injection of adrenalin on the first appearance of the submaxillary swellings and œdema of the mucous membrane of the pharynx. In a paper entitled the Mycotic Type of Bromodermia and Iododermia: Facial, Pharyngeal, and Intra-oral Œdema, and Swelling of Salivary and Thyroid Glands in Cases of Idiosyncrasy towards Iodides[1] one of the cases to which I referred was that of a married woman aged 43 years. Potassium iodide was ordered for bronchitic symptoms. After three 15-grain doses, all on Jan. 22nd, and accompanied by ten drops of digalen, the iodide had to be discontinued, as the patient developed facial œdema, especially about the orbits, and œdema of the floor of the mouth below the tongue, together with an urticaria-like eruption on the trunk and head (very little on the extremities). She also complained of severe headache. A small subcutaneous injection of adrenalin chloride on the morning of Jan. 23rd seemed to lessen these symptoms. The œdema of the floor of the mouth had practically disappeared by Jan. 24th, and the facial œdema and urticaria-like eruption were almost gone by Jan. 25th. It should be noted that the patient had for several years been subject to occasional attacks of urticaria and occasional œdema about the orbits. Moreover, it was ascertained that on one previous occasion she had manifested an idiosyncrasy towards potassium iodide. I am, Sir, yours faithfully,

London, W., April 9th, 1927. F. PARKES WEBER.

MENINGITIS ASSOCIATED WITH *B. PROTEUS*

To the Editor of THE LANCET

SIR,—The interesting paper of Drs. G. Bewley and E. S. Horgan in your last issue reminds me of the discovery of a bacillus of the same class in the cerebro-spinal fluid of cases of cerebro-spinal fever in the years 1915 and 1916. During the outbreak of cerebro-spinal fever amongst the troops at that period, I, as specialist sanitary officer of the Irish Northern Command, in conjunction with Lieutenant R. B. Purce and Dr. Georgina Darling, made bacteriological examinations of 129 cerebro-spinal fluids.[1] In 113 cases the meningococcus was discovered and in most cases cultivated, in five the tubercle bacillus, in one a streptococcus, in two the pneumococcus, and in one the typhoid bacillus.

In 30 separate cases we cultivated from the cerebro-spinal fluid a bacillus which we designated the *Bacillus meningitidis*. In 14 consecutive cases of our series this micro-organism was found, often at the first puncture, and at several of the consecutive punctures. In one case it was discovered at the first puncture and in this fluid no meningococci were found, but they were present in the cerebro-spinal fluid drawn off at a later date. In all cases the meningococcus was also present. Our bacillus was actively motile, liquefied gelatin, and had no action on glucose, lævulose, galactose, maltose, saccharose, lactose, starch, and mannite. Three strains produced acid in glucose media, but they differed from the other strains in not liquefying gelatin.

The only difference between our bacillus and that described by Drs. Bewley and Horgan is that ours failed to ferment glucose and lævulose. As we wrote at the time, "What the exact position of this micro-organism in a bacteriological classification should be will require further study, but it is evidently allied to the vibriones, the *B. fæcalis alkaligenes*, and the *proteus* group." The majority of the cases were under the care of Dr. A. Gardner Robb, of the Belfast City Fever Hospital, and we satisfied ourselves that we were not dealing with a mere contamination.

I am, Sir, yours faithfully,

W. JAMES WILSON.

Public Health Laboratories, Queen's University,
Belfast, April 16th, 1927.

VACCINES AND THE COMMON COLD

To the Editor of THE LANCET

SIR,—The results of the investigations by Ferguson, Davey, and Topley, published in your issue of April 16th, call, I think, for some comment, especially in view of the fact that an incomplete summary of the work appeared in a leading daily paper under the heading "Vaccination against Colds—Cure Better than Prevention." To the medical reader it is clear that the conclusion arrived at is simply that *three* doses of a stock vaccine containing eight different organisms failed to protect a certain population against the occurrence of common colds, but it is possible that the general public may imagine (*a*) that this is considered by bacteriologists in general to be the best method of protective anticatarrhal vaccination, and (*b*) that vaccination of any type is useless as a preventive of catarrhal infection

---

[1] Brit. Jour. Derm. and Syph., London, 1923, xxxv., 169–180.

[1] Brit. Med. Jour., 1916, ii., 900.

Many pathologists, with whom my own experience leads me to agree, would not expect to obtain any useful degree of immunity by the injection of only three doses of any anticatarrhal vaccine—stock or autogenous Here the analogy of antityphoid inoculation is fallacious On the other hand, it is found in practice that in people who are subject to catarrh pathogenic bacteria can be recovered with remarkable frequency from the nasopharynx, and often from the fæces also, and that a vaccine prepared from these almost always produces immunity for at least a year, and sometimes indefinitely, when a full course—roughly about 16 doses—is administered Furthermore, the success or failure is largely dependent on the presence or absence of nasal obstruction Consequently the nose should always be examined and appropriate surgical treatment advised if obvious lesions are found

The fact that the administration of a stock vaccine, without bacteriological examination of the patient, is more convenient does not prove that this method is useful The experiments recorded by these three observers afford satisfactory evidence to the contrary On another point, it is not stated whether the stock vaccine was made from repeatedly subcultured organisms Most of them are, in fact, so derived When it is necessary to use a stock vaccine it is, I submit, advisable that it should be prepared ad hoc from fresh bacteria, of which any large laboratory presumably has a supply

I am, Sir, yours faithfully,

Bedford square, W C , April 14th, 1927

ALLEGATIONS OF NEGLIGENCE IN CERTIFYING A MENTAL PATIENT

To the Editor of THE LANCET

SIR,—The leading article in THE LANCET of April 2nd, dealing with the Hume-Spry case, alludes to the need that more effect should be given to such protection as the medical certifier already possesses in such circumstances, while urging that prompt legislation should strengthen that protection

After a trial lasting some 15 days, Dr Percy Smith and Dr Watson, who were charged with having negligently signed a certificate in lunacy, have been completely vindicated by a special jury who stopped the case of their own accord without any direction from the learned judge How comes it that any doctor can be sued for negligence in the honest discharge of a duty which he owes to the public? He is not bound to certify anyone to be insane; but he must often do so, not only in the public interest, but in the interest of the patient himself who, if not placed under control, may suffer not only irreparable injury himself, but may be led to do that which, if he were in the possession of all his faculties, he would be the first to regret

The legislature has prescribed a form of protection for the medical profession, and those who were advising the defendants in the present case made the proper attempt to secure it for their clients, but without avail By S 330 of the Lunacy Act, 1890

> "If any proceedings are taken against any person for signing any certificate such proceedings may be stayed if the Court or Judge is satisfied that there is no reasonable ground for alleging want of good faith or reasonable care"

Shortly after the Hume-Spry action was launched an application was made pursuant to this section, on the part of the defendants, as a result of which a Master of the King's Bench stayed the action, and his order was affirmed by Mr Justice Bateson sitting as judge in chambers The Court of Appeal, however, reversed the learned judge's decision, holding that the matter must go before a jury The result is what we have seen A trial which must have involved enormous cost on both sides, and a number of baseless charges "random hurled" in open court against a number of innocent persons Is it too much to hope that the end of this case may encourage those in whom the power lies to stay such actions in future? Great judges in the past have inculcated that the power should be freely exercised

A few of the decisions of the courts in the matter may be usefully brought to recollection In the case of Hall *v* Semple (1862), 3 F & F, 337, Mr Justice Crompton, in charging a jury, said —

> Take me, then, as telling you, in point of law, that if a medical man assumes under this Statute (the Act then in force) the duty of signing a certificate, without making, and by reason of his not making, a due and proper examination, and such inquiries are necessary, and which a medical man in such circumstances ought to make and is called upon to make, not in the exercise of the extremest possible care but in the exercise of ordinary care, so that he is guilty of culpable negligence, and damage ensue, then that an action will lie, altho' there has been no spiteful or improper motive, and though the certificate is not false to his knowledge
> The question is whether there has been a neglect of that duty which a person in a case of this kind owes, not to interfere in a matter which touches the liberty of his fellow citizen without taking due care and making a careful examination and inquiry?"

It was after this that the protecting section appeared in the Lunacy Act of 1890 Its effect has been discussed in several cases In Shackleton *v* Swift ((1913), 2 K B, 304) a woman had been received as an alleged lunatic into a workhouse under an order of a relieving officer This order required the defendant, the master of the workhouse, to receive and detain the plaintiff for three days During that period the medical officer examined her and gave a certificate for her detention for 14 days After this she was detained for six days, when she was discharged again by order of the medical officer In these circumstances she sued the master of the workhouse, on the ground that her detention for more than three days was unauthorised in the absence of an order of a justice It was held that S 330 of the Lunacy Act above mentioned gave special protection to officers and others acting under its powers in cases where, although they might have misconstrued the Act, and although they might have done things which they had no jurisdiction to do, they had acted in good faith and in a reasonable manner In giving judgment, Lord Justice Vaughan Williams said —

> "Observe that this case is not a case under the powers of the Judicature Act and Rules We are not applying a general act to some case which happens to fall within its scope, what we are trying here is the question whether this action ought to be stayed having regard to the terms of the Lunacy Act, S 330 That is a very different thing to my mind to the case of a question under the Judicature Act and Rules whether an action ought to be stayed or not Here we are dealing with a particular subject matter, lunacy, and the Act of Parliament itself on the face of the Act—I do not so much say states as provides for, and assures, that public officers will be employed in carrying out the provisions of this Act of Parliament The Statute in S 330 seems to me to be a provision which recognises in itself the difficulty that may be experienced by the officers in carrying out this Act of Parliament"
>
> . The principle of the Act is if the proper officers carrying out the provisions of the Lunacy Act, 1800, have acted in good faith and with reasonable care, even though they have made a mistake—even though the Act of Parliament gave them no jurisdiction in the particular case, and therefore there was what was called the ground of want of jurisdiction, nevertheless they are to be protected That does not mean, to my mind, protected in the end after there has been an action or the action has been tried, it is a protection which relieves them from liability in my opinion before the action has been tried"

The meaning of the section was discussed once more in Everett *v* Griffiths (1920) 3 K B 161, where an action was brought against a chairman of a board of guardians and a doctor It was there pointed out that the act only imports that the medical practitioner shall act with reasonable care It does not say that he must act with reasonable skill, and in Everett v

Griffiths ((1920) 3 K B at p 184) Lord Justice Bankes said that it was a matter for considerable doubt whether the duty to act with reasonable care involved a duty to act with reasonable skill He said —

"To adopt the view that a medical man called in by a magistrate to express an opinion in reference to a person alleged to be a lunatic may be liable in damages for making an incorrect diagnosis, though he may have acted in perfect good faith and used all the care at his command, is to adopt a view which may render the working of the Act in many cases extremely difficult if not impossible a result which the legislature may have intended to avoid The Legislature intended that a person having the qualifications laid down in the Statute should be entitled to express an honest opinion arrived at with reasonable care on a matter of extreme difficulty and about which opinions might well differ without exposing himself to the risk of having his skill called in question before a jury and being possibly mulcted in heavy damages A medical man is under a duty towards the alleged lunatic to act in good faith and with reasonable care, but provided he has the qualifications prescribed by the Act, the degree of skill possessed by him or brought to bear upon the examination cannot be called in question"

In view of all this body of opinion it is a little difficult to see why the Court of Appeal refused to stay the action against the two practitioners who were so completely vindicated last week But it must be remembered that where the liberty of the subject is concerned the right to have the verdict of a jury is one which is regarded as almost sacrosanct

I am, Sir, yours faithfully,

April 2nd, 1927 JURIST

RHEUMATISM AND "GROWING PAINS"

To the Editor of THE LANCET

SIR,—It is in my opinion a grave reflection on the public health authorities that the great bulk of the general public is ignorant of, and totally uninstructed in, the serious significance of the vague pains in the limbs of a child or adolescent It is a frequent experience of general practitioners to discover irreparable heart lesions, the only rheumatic history obtainable being a diagnosis of "growing pains" by an aunt or a sympathetic neighbour A little while ago a child was brought to my surgery with aphasia, the loss of speech having been discovered that morning The child was found to be suffering from endocarditis with a mitral lesion which had given rise to no distress On inquiry I discovered that a fortnight previously the patient had complained of slight pains in the ankles which were rubbed with a "bottle" and dismissed as growing pains

The public must be instructed about the earliest symptoms of disease This is being admirably done in certain diseases and it remains for the authorities to see that the high mortality from heart disease is decreased by early treatment of its greatest causative factor—acute rheumatism

I am, Sir, yours faithfully,

ALFRED A MASSER, M B, Ch B

Penistone, April 11th, 1927

SIR Charles Hyde, Bart, has telephoned to the B B C station at Birmingham to say he was so impressed by the address on the work of Lord Lister broadcast by Sir Berkeley Moynihan on April 8th that he had decided to endow a bed in each of the five Birmingham hospitals—the General, the Queen's, the Children's, the Orthopædic, and the Women's Hospitals The address was broadcast from Leeds and relayed to all stations

BIRMINGHAM CRIPPLES —Mr Neville Chamberlain, Minister of Health, has opened a new centre for the out-patient and administrative work of the Birmingham Cripples' Union and Royal Orthopædic Hospital The centre is housed in the old Children's Hospital in Broad-street, which has been extensively remodelled, the additions including a series of workshops for the manufacture of surgical appliances The recent amalgamation of the Cripples' Union and the Orthopædic Hospital has created the third largest hospital charity in the city, with 268 beds and has necessitated the concentration of scattered offices, workshops, and out-patient departments The massage attendances last year numbered about 30,000, 5000 cases were treated otherwise, and there is a waiting-list of 500

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

The Easter Adjournment

THE House of Lords adjourned for the Easter recess on Tuesday, April 12th until April 28th Among the Bills to which the Royal Assent was given by commission were the Royal and Parliamentary Titles Act and the Sale of Food and Drugs Act The House of Commons adjourned on Thursday, April 14th, until Tuesday, April 26th

HOUSE OF COMMONS

TUESDAY APRIL 12TH

Finances of Scottish Maternity Hospitals

SIR ARCHIBALD SINCLAIR asked the Secretary of State for Scotland whether he was aware that the new regulations governing the training of midwives had increased the financial burdens on Scottish maternity hospitals, whether the financial difficulties experienced by these hospitals had been considered by him, and whether he was now prepared to recommend to Parliament that grants should be given to Scottish maternity hospitals commensurate with those given to similar hospitals in England —SIR JOHN GILMOUR replied I am aware that the receipts of the Scottish maternity hospitals have been diminished by a decrease in the amounts received in fees from pupil midwives The grants referred to in the question are not, of course, grants to the hospitals as such, but are grants for the purpose of aiding students undergoing a particular course of training I think that the diminution in entrants may be attributed to the economic consideration that the average earnings of a registered midwife in Scotland do not provide a living wage rather than to the regulations of the Central Midwives Board (Scotland) which lengthened the period of training I have, however, taken steps to have the position of the hospitals carefully and sympathetically considered, but I am not yet in a position to make any recommendation to Parliament

Accidents in Mines

Mr GRUNDY asked the Secretary for Mines what was the number of fatal accidents in mines in the months of January, February, and March, 1926, and what was the number of non-fatal accidents during the same period, what had been the number of fatal accidents in mines in the months of January, February, and March in 1927, and the number of non-fatal accidents for the same period, and the proportion to the number employed in both periods —Colonel LANE-FOX replied During the first three months of 1926 there were 306 deaths from accidents at mines under the Coal Mines Act and 1214 persons were seriously injured The death-rate per 1000 persons employed was 0 27 and the serious injury-rate 1 07 The corresponding figures for the first three months of 1927, which were increased by the serious disasters at Cwm and Bilsthorpe, were 324, 1291 —0 31 and 1 25—respectively I regret that comparable figures as regards the less serious non-fatal accidents are not yet available

THURSDAY, APRIL 14TH

Expenditure on Additional Insurance Benefits

SIR JOHN POWER asked the Minister of Health the total expenditure during 1926 in respect of each class of additional benefit under the National Health Insurance Act —Mr CHAMBERLAIN replied The total expenditure during 1926 in England and Wales in respect of each class of additional benefit under the National Health Insurance Act—other than additional benefits which take the form of increases of ordinary cash benefits—was approximately as follows —

	£
Dental treatment	1,146 700
Ophthalmic treatment	155,900
Treatment in hospitals	228,800
Treatment in convalescent homes	43,400
Surgical appliances	33,900
Provision of premises for convalescent homes	9,700
Provision of nurses	7,100
Repayment of contributions	12,800
Payments in want or distress	8 500

Note —The amount of additional benefit paid by way of increases of ordinary cash benefits (sickness, disablement, and maternity) is not separately recorded

Poor-law Relief Statistics

Mr COMPTON asked the Minister of Health the number of persons in England and Wales in receipt of Poor-law relief at Dec 31st, 1924, 1925 and 1926 respectively, and the amount of moneys paid and relief in kind granted during the last week of the above-named years —Mr CHAMBERLAIN replied The following is the information asked for The numbers of persons in receipt of Poor-law relief (excluding lunatics in asylums) in England and in Wales at the end of December in the years mentioned were —

	England excluding Monmouthshire	Wales and Monmouthshire
In 1924	982,021	111,031
In 1925	1,194,426	150,597
In 1926	1,283,801	222,719

The average weekly amount of out-door relief in money and kind granted during December in those years was —

	England excluding Monmouthshire £	Wales and Monmouthshire £
In 1924	231 952	30,379
In 1925	314,521	38,788
In 1926	367,153	66,426

The figures for Wales and Monmouthshire are those for the union counties in Wales and Monmouthshire

Local Authorities and Mosquito Pests

Mr DAY asked the Minister of Health if he was aware that certain councils were supplying householders with a pamphlet on how to fight the mosquito menace, and would he consider instructing all health authorities to supply householders with similar literature —Mr CHAMBERLAIN replied The attention of medical officers of health throughout the country has already been drawn to the pamphlet published by the British Museum, which gives advice to local authorities as to the best measures to combat the mosquito pests

The Traffic in Women and Children

Mr CECIL WILSON asked the Secretary of State for Foreign Affairs when it might be hoped that the replies of the various Governments regarding Part II of the Report on the Traffic in Women and Children were likely to be received, and how soon thereafter publication might be expected —Mr LOCKER-LAMPSON (Under Secretary for Foreign Affairs) replied My right hon friend has no means of forecasting the action of foreign Governments in this matter, but he hopes that the Council of the League will be in a position to take a decision at its next meeting in June

Inspection of Casual Wards

Captain BOURNE asked the Minister of Health whether there were now any casual wards in England or Wales where the guardians did not supply night clothing for both men and women, whether in the unions which supplied night clothing, after being used for one inmate, such night clothing was always washed before being given to another, and whether he had, since Feb 17th, 1925, arranged for evening visits to casual wards by a woman medical inspector of the Ministry of Health —Mr CHAMBERLAIN replied In June, 1926, there were 22 such casual wards I have every reason to believe that this number has been substantially reduced The women inspectors of the Ministry (who hold a nursing but not a medical qualification) do inspect the casual wards and I will arrange for them to do so from time to time in the evening

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON —An ordinary comitia of the College was held on April 11th, Sir John Rose Bradford, the President, in the chair An abstract report was presented of the extraordinary general meeting of the College held on Feb 10th, 1927, at which the draft of the revised bye-laws was submitted to the comitia for the second time and, with certain small amendments, was approved to be the bye-laws of the College for the time being

The President then delivered his annual address, in which he reviewed the work of the College during the past year He pointed out that there were now 379 Fellows There was a considerable increase in the number taking the membership, the total number of Members now being 830 as against 732 a year ago He mentioned the honours conferred by the King upon Fellows, Members and Licentiates of the College, including that of K C B upon Lord Dawson of Penn, the K B E upon Sir Stanley Hewitt, and the knighthood upon Dr Henry Head He also alluded to the gifts made to the College, including a replica of the portrait of Sir Richard Douglas Powell, painted by Mr Spencer Watson and given by Colonel Sir Douglas Powell, a silver claret jug from Mr H T Herring, and a china tea service from Mrs Alec Tweedie, which had been a presentation to Dr Alexander Tweedie in 1802 He also referred to the revision of the bye-laws and to the power that the College now assumed of granting Honorary Fellowships in special circumstances

The President then delivered obituary addresses upon the career and work of the 15 Fellows who had died in the past year—namely, Dr F S Palmer, Dr E S Reynolds, Sir John Williams, Sir W B Leishman, Sir F W Mott, Dr John Thomson of Edinburgh, Dr Robert Hunter Steen Dr R H Cole, Dr J G Adams, Dr James Barry Ball, Dr Francis Warner, Dr Thomas Claye Shaw, Sir Isambard Owen, Dr Llewellyn Powell Phillips, and Dr Thomas R Bradshaw

Sir David Ferrier, the senior Fellow present, then proposed a vote of thanks to the President and asked, at the special wish of the College, that he would allow his address to be printed and circulated

Sir John Rose Bradford was re-elected President for the ensuing year

Diplomas in tropical medicine were granted, jointly with the Royal College of Surgeons, to the following 24 candidates who have passed the required examination

S Annecke, E G Anthonisz, A C L O'S Bilderbeck, Catherine V Burne, N P Dalal, T B Gilchrist, R D Gross, Kathleen M Halloran, R G Keays, H H W Kumm, F R Lockhart, A D Loganadan, P H Martin, F R L Miller, Margaret M Nolan, J Portelli, Helen M Russell, E G Sayers, H M Shelley, Viva E K Stuart H S Townsend, Bertha Williamson, C J Wylde, and W. A Young

ROYAL COLLEGE OF SURGEONS OF EDINBURGH —At recent examinations out of 10 candidates entered the Final Dental Professional Examination the following 16 passed and were granted the Diploma of L D S R C S Edin —

John McAra, A L Cadenhead, David Logie, Bernard Silverston W G Thow, Sri Kishan Kapur, R G Chambers, S W Cruickshank, V L Shearer, A R Ferguson, C C Gair N I Macmillan A J de Villiers, E H B Gooch, T T Jamieson, and Thomas MacLaren

BRITISH PATHOLOGISTS ASSOCIATION —At a meeting of the council of this Association held on April 9th, the following resolution was adopted —

"That inasmuch as it is confidently expected that steps will shortly be taken by the Ministry of Health for the provision of pathological investigations for patients insured under the National Health Insurance Acts, and furthermore, inasmuch as any arrangements made to this end at this time by individual National Health Insurance authorities must necessarily influence the matter when it comes up for final settlement, it is in the opinion of the British Pathologists Association in the highest degree inadvisable that any such local arrangements should be entered upon at this time except upon the basis of payment per examination performed and not by payment of lump sum irrespective of work done further the Association considers that the fees charged should be such as to cover adequately the real cost of the work performed otherwise the service becomes a charge upon the funds of the institution undertaking it"

A schedule of proposed fees for pathological investigations for insured patients is now in course of preparation by the Council and will be circulated among members of the Association when complete These fees, it is stated, are based upon a carefully prepared costing scheme and may be regarded as representing the lowest charges at which the procedures indicated can be performed

---

LEWISHAM NURSES' HOME —A beginning has been made in the erection at Lewisham Poor-law hospital of a home for the accommodation of 211 members of the nursing staff at a cost of £129,000 The home will include a lecture-room and a library and each nurse will have a separate bedroom

BRITISH EMPIRE CANCER CAMPAIGN —Lord Cave presided at a quarterly meeting of the Grand Council on April 12th The council received the resignation of the organising adviser to the campaign, Lieut-General Sir John Goodwin, F R C S, who has been appointed Governor of Queensland —An application for affiliation was received from the National Cancer Campaign (Ireland), which has just been formed, and which includes representatives both of Ulster and the Free State The application was granted, and good wishes were sent to the new organisation —Grants of £298 and £900 respectively were made for apparatus and for the upkeep for one year of the radiological cancer research department of the Middlesex Hospital, and a further grant of £3000 was approved in support of the maintenance of the general cancer research department of that hospital —The grant of £100 to Mr E Nevill Willmer, of Manchester University, was renewed for another year to enable him to continue work on tissue culture and a further grant of £300 was made to Prof C E Walker, of Liverpool, to enable him to continue cancer research

UNIVERSITY OF LONDON —At a meeting of the Senate held on March 23rd, it was resolved that a statement be published to the effect "that candidates for the degree of B D S will be required to pass the First Examination for Medical Degrees before proceeding to the Second Examination in Dental Surgery"

Three lectures on Sensation and the Sensory Pathway will be given by Dr J S B Stopford, F R S, professor of anatomy in the University of Manchester, at University College on May 3rd, 4th, and 6th, at 4 30 P M

Four lectures on the Autonomic Nervous System will be given by Dr R J S McDowall, professor of physiology in the University, at King's College, at 5 P M, on Tuesdays, May 3rd 10th, 17th, and 24th

A course of four lectures on the Menstrual Function, its Physiology and Pathology will be given by Mr H Beckwith Whitehouse, professor of midwifery and diseases of women in the University of Birmingham, at the London (R F H) School of Medicine for Women on Mondays, May 9th, 16th, 23rd, and 30th, at 5 30 P M.

Dr Andrew Balfour will take the chair at the first of four lectures on National, Regional, and Town Development Planning to be given by Mr W H McLean, late Egyptian and Sudan Government Services, at University College on Tuesdays, May 10th, 17th, 24th, and 31st, at 5 30 P M.

Three lectures on Problems of Mental Work will be given by Prof A. Michotte, of the University of Louvain, at King's College on May 10th, 12th, and 13th, at 5 30 P M

Three lectures entitled Some Surgical Problems will be given by Mr John Fraser, regius professor of clinical surgery in the University of Edinburgh, at the Middlesex Hospital Medical School on Monday, Tuesday and Wednesday, May 16th 17th, and 18th, at 5 P M.

S P James, M.D Some Methods and Problems of Malaria Research 26th —Prof Hugh MacLean Insulin in the Treatment of Diabetes and some other Nutritional Disturbances June 2nd —Prof C A Lovatt Evans, F R S The Alkalinity of the Blood 9th —Prof B J Collingwood Molecular Movement in the Living Body These lectures are open to doctors and medical students without fee

DONATIONS AND BEQUESTS —Miss Agnes Russell, Muirfield, Castlehead, Paisley, left £1000 each to the Royal Alexandra Infirmary, Paisley, the Paisley Industrial School the Salvation Army, and Quarries's Orphan Home, and £500 to several other charities including the Paisley Convalescent Home —Mr Thomas Cooper, J P, Kingsland, Shrewsbury, left £1000 each to several institutions including the Royal Salop Infirmary for the endowment of a "Thomas Cooper" bed, and the National Children's Home and Orphanage for a "Thomas Cooper" bed, and £250 to the Eye Ear and Throat Hospital for Shropshire and Wales —Mr Joel Settle, The Hill, Alsager, Cheshire left £1000 to the North Staffs Infirmary, Stoke-on-Trent Salford Royal Hospital has received £2000 from the Booth Charities and the Salford and District Nurses' Home, £400 The donations to other hospitals amounted to £1310 during the last week of the above-named years —Mr CHAMBERLAIN replied The following is the information asked for The numbers of persons in receipt of Poor-law relief (excluding lunatics in asylums) in England and in Wales at the end of December in the years mentioned were —

	England excluding Monmouthshire	Wales and Monmouthshire
In 1924	982,021	111,031
In 1925	1,194,426	150,597
In 1926	1,283,801	222,719

The average weekly amount of out-door relief in money and kind granted during December in those years was —

	England excluding Monmouthshire £	Wales and Monmouthshire £
In 1924	231 952	30,379
In 1925	314,521	38,788
In 1926	367,153	66,426

The figures for Wales and Monmouthshire are those for the union counties in Wales and Monmouthshire

Local Authorities and Mosquito Pests

Mr DAY asked the Minister of Health if he was aware that certain councils were supplying householders with a pamphlet on how to fight the mosquito menace, and would he consider instructing all health authorities to supply householders with similar literature —Mr CHAMBERLAIN replied The attention of medical officers of health throughout the country has already been drawn to the pamphlet published by the British Museum, which gives advice to local authorities as to the best measures to combat the mosquito pests

The Traffic in Women and Children

Mr CECIL WILSON asked the Secretary of State for Foreign Affairs when it might be hoped that the replies of the various Governments regarding Part II of the Report on the Traffic in Women and Children were likely to be received, and how soon thereafter publication might be expected —Mr LOCKER-LAMPSON (Under Secretary for Foreign Affairs) replied My right hon friend has no means of forecasting the action of foreign Governments in this matter, but he hopes that the Council of the League will be in a position to take a decision at its next meeting in June

Inspection of Casual Wards

Captain BOURNE asked the Minister of Health whether there were now any casual wards in England or Wales where the guardians did not supply night clothing for both men and women, whether in the unions which supplied night clothing, after being used for one inmate, such night clothing was always washed before being given to another, and whether he had, since Feb 17th, 1925, arranged for evening visits to casual wards by a woman medical inspector of the Ministry of Health —Mr CHAMBERLAIN replied In June, 1926, there were 22 such casual wards I have every reason to believe that this number has been substantially reduced The women inspectors of the Ministry (who hold a nursing but not a medical qualification) do inspect the casual wards and I will arrange for them to do so from time to time in the evening

---

LEWISHAM NURSES' HOME —A beginning has been made in the erection at Lewisham Poor-law hospital of a home for the accommodation of 211 members of the nursing staff at a cost of £129,000 The home will include a lecture-room and a library and each nurse will have a separate bedroom

The council received the resignation of the organising adviser to the campaign, Lieut -General Sir John Goodwin, F R C S, who has been appointed Governor of Queensland —An application for affiliation was received from the National Cancer Campaign (Ireland), which has just been formed, and which includes representatives both of Ulster and the Free State The application was granted, and good wishes were sent to the new organisation —Grants of £208 and £900 respectively were made for apparatus and for the upkeep for one year of the radiological cancer research department of the Middlesex Hospital, and a further grant of £3000 was approved in support of the maintenance of the general cancer research department of that hospital —The grant of £100 to Mr E Nevill Willmer, of Manchester University, was renewed for another year to enable him to continue work on tissue culture, and a further grant of £300 was made to Prof C E Walker, of Liverpool, to enable him to continue cancer research

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON —An ordinary comitia of the College was held on April 11th, Sir John Rose Bradford, the President, in the chair An abstract report was presented of the extraordinary general meeting of the College held on Feb. 10th, 1927, at which the draft of the revised bye-laws was submitted to the comitia for the second time and, with certain small amendments, was approved to be the bye-laws of the College for the time being

The President then delivered his annual address, in which he reviewed the work of the College during the past year He pointed out that there were now 379 Fellows There was a considerable increase in the number taking the membership, the total number of Members now being 836, as against 732 a year ago He mentioned the honours conferred by the King upon Fellows, Members and Licentiates of the College, including that of K C B upon Lord Dawson of Penn, the K B E upon Sir Stanley Hewitt, and the knighthood upon Dr Henry Head He also alluded to the gifts made to the College, including a replica of the portrait of Sir Richard Douglas Powell, painted by Mr Spencer Watson and given by Colonel Sir Douglas Powell, a silver claret jug from Mr H T Herring, and a china tea service from Mrs Alec Tweedie, which had been a presentation to Dr Alexander Tweedie in 1802 He also referred to the revision of the bye-laws and to the power that the College now assumed of granting Honorary Fellowships in special circumstances

The President then delivered obituary addresses upon the career and work of the 15 Fellows who had died in the past year—namely, Dr F S Palmer, Dr E S Reynolds, Sir John Williams, Sir W B Leishman, Sir F W Mott, Dr John Thomson of Edinburgh, Dr Robert Hunter Steen, Dr R H Cole, Dr J G Adams, Dr James Barry Ball, Dr Francis Warner, Dr Thomas Clave Shaw, Sir Isambard Owen, Dr Llewellyn Powell Phillips, and Dr Thomas R Bradshaw

Sir David Ferrier, the senior Fellow present, then proposed a vote of thanks to the President and asked, at the special wish of the College, that he would allow his address to be printed and circulated

Sir John Rose Bradford was re-elected President for the ensuing year

Diplomas in tropical medicine were granted, jointly with the Royal College of Surgeons, to the following 24 candidates who have passed the required examination

S Annecke, E G Anthonisz, A C L O'S Bilderbeck, Catherine V Burne, N P Dalal, T B Gilchrist, R D Gross, Kathleen M Halloran, R G Keays, H H W Kumm F R Lockhart, A D Loganadan, P H Martin, F R L Miller, Margaret M Nolan, J Portelli, Helen M Russell, E G Sayers, H M Shelley, Viva E K Stuart H S Townsend, Bertha Williamson, C J Wylde, and W A Young

ROYAL COLLEGE OF SURGEONS OF EDINBURGH —At recent examinations out of 10 candidates entered the following 16 passed the Final Dental Professional Examination and were granted the Diploma of L D S R C S Edin —

John McAra, A. L Cadenhead, David Logie, Bernard Silverston W G Thow, Sri Kishan Kapur, R G Chambers, S W Cruickshank, V L Shearer A R Ferguson, C C Gair N I Macmillan A J de Villiers, E H B Gooch, T T Jamieson, and Thomas MacLaren

BRITISH PATHOLOGISTS ASSOCIATION —At a meeting of the council of this Association held on April 9th, the following resolution was adopted —

> "That inasmuch as it is confidently expected that steps will shortly be taken by the Ministry of Health for the provision of pathological investigations for patients insured under the National Health Insurance Acts, and furthermore, inasmuch as any arrangements made to this end at this time by individual National Health Insurance authorities must necessarily influence the matter when it comes up for final settlement, it is in the opinion of the British Pathologists Association in the highest degree inadvisable that any such local arrangements should be entered upon at this time except upon the basis of payment per examination performed and not by payment of lump sum irrespective of work done further the Association considers that the fees charged should be such as to cover adequately the real cost of the work performed otherwise the service becomes a charge upon the funds of the institution undertaking it"

A schedule of proposed fees for pathological investigations for insured patients is now in course of preparation by the Council and will be circulated among members of the Association when complete These fees, it is stated are based upon a carefully prepared costing scheme and may be regarded as representing the lowest charges at which the procedures indicated can be performed

UNIVERSITY OF LONDON.—At a meeting of the Senate held on March 23rd, it was resolved that a statement be published to the effect "that candidates for the degree of B D S will be required to pass the First Examination for Medical Degrees before proceeding to the Second Examination in Dental Surgery."

Lennox Castle as Poor-law Hospital —Glasgow Parish Council has purchased Lennox Castle and 1300 acres for about £25,000 as a Poor law institution The castle, until recently one of the residences of Mr Peareth-Kincaid-Lennox, was built nearly a century ago, is of great size, and is in good condition. It is some seven miles from Glasgow

Notes, Comments, and Abstracts.

RADIOLOGY IN RELATION TO COMPENSATION CASES.[1]

BY A. E. BARCLAY, M.D. CAMB., D.M.R.E.,
HON. MEDICAL OFFICER, X RAY AND ELECTRICAL DEPARTMENTS, ROYAL INFIRMARY, MANCHESTER.

MANY will remember the days when an X ray picture was regarded as a pure luxury. In this country the first shadow of the part radiology would take, not only in medicine but in the public mind, was cast by a legal action against a distinguished surgeon. It was a case of shoulder injury in which a clinical diagnosis of a fracture had been made. Later on a radiograph showed that there was a dislocation as well as a fracture, and the lawyers got busy proving negligence for the non-use of X rays. Negligence was proved to the satisfaction of the court and the damages awarded were very heavy. This case, and many others that followed, forced the use of radiology on to the medical profession, willy nilly, if only for their own protection, and to-day thousands of patients are examined radiographically, both in hospital and private practice, not to make a diagnosis but simply to protect the doctor. Certainly this examination often reveals things that were not expected, so that we cannot say that all this work is unnecessary, for clinically we never know in which cases an X ray examination will not be of assistance. Hence it comes about that practically every accident in which there is suspicion of injury to bones passes through the hands of the radiologist. In a large proportion of them the question of compensation is raised, and the X ray evidence is regarded as the deciding factor in the award of compensation.

Radiology in Court.

For the practical purposes of compensation work, the X ray picture is one of bones, the skeletal structures; it takes little or no account of the ligaments and other structures which are of equal if not greater importance as factors producing disability. Perhaps it is not for a radiologist to emphasise this fact, which should be obvious even to a layman, but I have seen so many cases pass through the courts, and compensation awarded, denied or reduced simply on what is shown radiographically, the medical men present assenting, that I feel I must stress this point. Let me take two cases. A lady was injured in a motor smash, and the radiograph showed that not only were the rami of the pubes and ischium shattered on the one side, but that the ilium had slipped up, this being allowed for by a fracture of the sacrum, the outer part of which had gone upwards, probably impacted with the body of the fifth lumbar vertebra. I have seldom seen such an extensive injury, and you can hardly credit it, but it is a fact that this lady walked into my rooms three months after the accident as if there was nothing the matter, although one leg is fully an inch short. I understand that she leads an almost normal life, doing her house work practically unaided. The case is due in the courts this month, and there is *no* doubt that she will get very large compensation, simply because, anatomically, the injury is so very extensive, although the actual functional disability is astonishingly trifling.

Then we have the miner with a back injury, one of very many similar cases, a man whose sweat pours off him as he gets on to the couch, a man with a family, with every inducement, and apparently with every wish, to be at his work, and in whom we cannot find a trace of any injury to the bones, with the result that he is written down as a "lead swinger," and his compensation is reduced in the hope of forcing him back to work. Not that I consider that all these men are genuinely disabled; far from it, but my point is that the radiographic evidence is not the one and only guide. It is, in fact, most fallacious. Surely it is on the functional *disability* that compensation should be based and, in my view, far too great weight is attached to the X ray findings in attempting to arrive at justice in these exceedingly difficult cases. The X ray picture with its positive demonstration of bony injury is often the only tangible factor that can be placed before the judge and jury, and it is little wonder that they seize upon this, probably the only definite point that can be raised in the whole case. And just as surely, if the X ray plates do not show any bony injury, the case is prejudiced from the start.

Nothing is more difficult in the whole field of justice than these compensation cases, in which the plaintiff, his legal advisers and, I regret to say it, his medical witnesses also, magnify, wittingly or otherwise, every point that may tell in the plaintiff's favour, while the defence seize every opportunity of depreciating the statements that are made. Justice may indeed be served, but it is handicapped in a manner that frequently makes the path of the applicant far from easy, and leaves many an embittered and seriously disabled man feeling that he has not been justly dealt with. If there is one factor more than another that produces malingerers it is the thought of compensation, and many an honest man, knowing of the fate of others, has stooped to deception of which he would never have dreamed had it not been for the thought of the assessment of his case in a court, and before arbitrators whom he knows he must try to impress with the severity of his disabilities. There is something wrong with the whole system, particularly with the part played in it by medical men who, even with the best intentions, cannot but be partisans. I have even known a case in which a medical man, giving evidence in a case of neuritis, stated that there was no X ray evidence of this complaint, a point on which, by no stretch of imagination could the X ray examination throw a particle of light. I do not wish to belittle the value of the X rays in medicine, but I hold very strongly that the place of radiology in compensation is often on a wrong footing, being regarded as a court of appeal by consent of all concerned, whereas it is only competent to give information as to skeletal structures, and, in the nature of things, can hold next to no knowledge of function and vital processes.

Assessment of Disability out of Court.

I should like to see the whole of the medical side of all cases dealt with, and the disability assessed, outside the courts of law by medical men who are entirely independent. The medical referee is a step in the right direction, but I would go further and divorce the assessment of disability entirely from the legal liability side of the case by the establishment of competent tribunals under the chairmanship of a well qualified and experienced medical man. These tribunals might be empowered to accept written medical opinions or take evidence from medical men themselves if necessary. The patient would be examined by them and they would assess the disability, unhampered by the legal, the sentimental aspects, and the partisanship that are inevitable under the present system. It is accepted by the courts that the medical man is the proper person to give an opinion on this vital subject of disability, yet he stands in the box as a witness for the plaintiff or the defence. The result is seldom satisfactory to the medical man, for, in the mass of mixed medicine and legality, with its quibbles, it is almost a chance whether the judge and jury take an over-serious or over-lenient view of the case. The chanciness of the verdict and the assessment of damages are a ruling factor in the minds of all lawyers who deal with these cases. I have frequently heard it stated that it would be no use bringing the case forward if So-and-so were the judge, but that there would be a good chance in another court, meaning thereby that one judge set less store by the statements of expert medical witnesses than did the other judge. This chanciness was particularly well brought out in an assize case a few years back, in which a lady had received a severe acute burn of her neck from the application of X rays in a large hotel, where a progressive management had installed a plant, and placed it in the hands of the bath attendant. It was a severe burn, and one that would certainly leave considerable disfigurement, but, in all probability, little else. We sat in consultation with counsel in his room before the opening of the case. A message came from the counsel for the defence for a conference, and presently the counsel for the plaintiff came back to ask advice as to whether to settle or not for what I considered a very large sum plus costs. The decision to accept was based not on the disability and disfigurement, but on the possibility of cancer occurring in the scar, and the effect of such a possibility on the mentality of the judge who was sitting. The defence, we found afterwards, were quite certain that the cancer possibility would be a strong point in the pleadings, whereas the experience of the radiologists advising the plaintiffs was that they had never known cancer to occur in the scar resulting from an *acute* X ray burn, and they had advised strongly that this possibility should not be stressed. Had it not been for the uncertainty on the purely medical side, and the legal argument that would probably have centred about a remote and probably negligible possibility, the damages in this case would have been of a much more modest nature, and, I think, justice would have been better served.

It would not, I suppose, be possible completely to divorce the medical side of the case from the legal, but, in such an instance as this, the medical side could be tried and witnesses called before a medical tribunal, and the independent medical chairman of that tribunal would be the one and only medical man who would be called in the legal proceedings, which would thereby be considerably shortened. So also in the ordinary workman's compensation pleadings, the disability would be assessed on a percentage basis in relation to the man's employment, and this would be given to the court *after* it had determined the purely legal side of the liability, any further information being provided by the independent chairman of the medical court. Incidentally, such a scheme, if it were practicable, would save the hard-wrought medical man from many weary hours, or even days, waiting in or about the courts for a summons to go into the witness-box In many of the compensation cases there is no legal side at all, to bring these cases into the courts purely for an assessment is costly, and often unsatisfactory *I understand that in America the expense took on such proportions that the insurance companies could stand it no* longer, and, presumably by mutual consent, they set up their own medical scheme, the medical officers of the societies concerned assessing the disability, with the result that this type of litigation has been reduced to reasonable if not negligible proportions

---

[1] Being the substance of a post-graduate lecture given at the Infirmary.

Conclusions

The X ray plate only shows skeletal structures, yet it is often used in Court as the deciding factor in compensation in cases in which the injury may be one of the soft parts which do not show on the plate Too much reliance is placed on the X ray evidence in cases of injury The time has come when the system of assessing compensation in a legal court should be reconsidered, and it is proposed that the disability should be assessed before a purely medical tribunal whose evidence should be presented to the legal court by an independent medical chairman

DRUG ADDICTION IN KOREA

A REPORT on the treatment of morphia addicts in Chosen (Korea) has recently been issued by the Japanese Government

Opium-smoking has long been common in Chosen, especially in districts adjoining China The former Korean Government tried to suppress the habit, but without much success After the Japanese annexation, however, strong measures were taken to suppress it, and at the same time medical treatment was given to addicts Their number gradually decreased and the situation so much improved, that *in September, 1914, the Government decided to adopt absolute prohibition As many addicts as possible* were collected for medical treatment, and the result is that to-day opium-smoking has been all but suppressed in Chosen

At the same time, however, there has been a rapid increase in the number of persons using morphine, cocaine, and other similar drugs It is stated that this practice was originally taught by foreign missionaries to addicts of opium-smoking so as to rid them of their habit Be that as it may, the extent of the vice is now serious, and the authorities have made an order prohibiting the use of the drugs in the provinces, where it is most common In coöperation with local philanthropic bodies, they are also taking steps to cure addicts In Keiki, for instance, an infirmary has been established at public expense since 1925, where compulsory and general medical treatment is given The results at this and other centres are described as excellent

As might be expected, however, there are many patients who relapse after treatment, and it is considered next to impossible to suppress drug-taking unless rigorous measures are adopted Addicts, moreover, are generally adept in tempting others, and it is feared that the vice will again spread With a view to its complete suppression, the Government of Chosen is therefore considering a plan to enforce medical treatment of addicts throughout the peninsula, and mete out severe punishment to anyone using morphine and other dangerous drugs

THE APPROACH TO PAINTING[1]

Mr Bodkin is a Trustee of the National Gallery of Ireland, and has probably had borne in upon him, as it is borne in upon most of those who direct or take charge of big public collections, that a vast proportion of those who go to look at pictures do not enjoy themselves as they might, not having any proper ideas of the way to look, of what to expect and, in short, of how to derive pleasure through the eye The book is divided into two parts, in the first of which a series of chapters describes the philosophical, the analytical, the technical, and the casual approach of pictures, and concludes with an amusing description of what is called "the approach by siege" The advice is given in this chapter to discard the view held by many critics and some princes of art that ability to appreciate painting is a chance gift, and to recognise that the more experience of life that is brought to assist the judgment of the spectator the better will be the chance of sharing with the painter his meaning, and so of appreciating his work fully The recommendation is given to sit down before a picture, to besiege it, to rack it with questions, rather than to approve it or reject it in a brief scrutiny or for other than reasons that appear satisfactory to the inspector The second part of the book describes this method when applied to some 20 famous pictures ranging in date through early Florentine art, the Venetian epoch, the Flemish, Spanish, and French schools of the seventeenth and eighteenth century, and ends with an analysis of a popular portrait by Gainsborough and a famous landscape by Corot

WAS SPALLANZANI A PRIEST?

IN his Discourse at the Lister Centenary Prof W Bulloch quoted a famous saying of Lazzaro Spallanzani giving him the title "Abbate" A correspondent wrote to inquire whether it is now beyond doubt that the great naturalist, physiologist, and scholar had also taken holy orders Prof. Bulloch replies "There is no doubt as to the correctness of calling Spallanzani 'Abbate' He is so designated, sometimes Abate, sometimes Abbate, on all his works I have before me as I write —

1 Fisica animale et vegetabile del Sig Abate Spallanzani, 1782

2 Dissertazioni di fisica animale e vegetabile dell Abate Spallanzani, 1780

3 Dei fenomeni della circolazione dell Abbate Spallanzani, 1773

4 Dell' Azione del Cuore ne vasi sanguigni dell Abate Spallanzani Sacerdote della Congregazione della B vergine, e S Carlo di Modena.

"Pavesi's book entitled 'L'Abbate Spallanzani à Pavia 1901,' contains an exhaustive examination of the documents relating to Spallanzani in Pavia He tells us (p 11) that 'he officiated daily at mass at S Epifanio which proves that he had taken holy orders' When mass was stopped at S Epifanio, Spallanzani asked to be transferred to the mass at Jesus, which was the University Chapel after the Expulsion of the Jesuits It has not been found where Spallanzani was ordained, but it is probable that he became a priest at Reggio when a young man

"Some years ago," Prof Bulloch continues "I went rather fully into this question with an eminent legal authority on the Catholic Church who told me that unless Spallanzani *had been ordained as a priest he could not possibly have* taken part in a mass as we know he did Of course he is often called Abbé, which was a kind of courtesy title in France, not necessarily an ordained priest The French word 'Abbé' is not an exact translation of 'Abbate,' nor is our English 'Abbot' Hence I thought it best to give Spallanzani the title which he himself used"

ADVICE TO GIRLS OF SCHOOL AGE

Dr Hilda Halliday has written a small book[1] on health and habits for the use of senior girls in elementary schools In style and scope it is admirably suited to its purpose, and as Prof H R Kenwood says in his foreword, it will help to make young girls realise the need for self-preparation for the duties of life, and direct their minds to a purpose and duty in motherhood which is all too little recognised

This is one object of the book, another is to offer practical advice to girls who often have considerable responsibilities in guiding the early stages of development of younger members of the family The infant's first lessons are connected with the formation of good physical habits—regular hours for sleep, feeding, bodily functions, and exercise—and a basis of such habits is to lead on to a superstructure of good principles Dr Halliday is no believer in the theory that everything is to be made soft and easy for the child, rather he is to be encouraged to develop resource, pluck self-control and a sense of fair play—qualities which he is usually ready to display until he has been spoiled by the interference of adults "Children are courageous about pain unless they are 'let down' by their elders", "Remember that he (the four-year-old) is an intelligent person, and don't put him off with a snub or an untruth", "A promise made to a child must be kept, or else a reasonable explanation must be given"—these are ideas which are well worth implanting in the adolescent mind

The book is attractive in appearance, it has short chapters with inviting titles, the type is clear, and the excellent illustrations are reproduced from old masterpieces The ground covered is necessarily limited, and some supplementary instruction on such matters as the control of the body and the emotions—hardly more than hinted at by Dr Halliday—will need to be given But the teaching is sound and is calculated to appeal to the elder school-girl, in whose hands the book may safely and profitably be placed

ON THE

IMPORTANCE OF TOXÆMIA

DUE TO ANAEROBIC ORGANISMS IN ACUTE INTESTINAL OBSTRUCTION AND PERITONITIS.

Delivered at the Royal College of Surgeons of England on Feb. 21st, 1927,

BY B. W. WILLIAMS, B.M. OXF., F.R.C.S. ENG.,
FIRST ASSISTANT, CLINICAL SURGICAL UNIT,
ST. THOMAS'S HOSPITAL

IN dealing with a problem as ancient as the toxæmias of acute intestinal obstruction and peritonitis one finds that every possible clinical observation has been made. I have nothing original to add to these clinical observations. They are merely presented in a special form and sequence in support of a theory of the origin of toxæmia.

In the terminal stages of most fatal cases of acute peritonitis paralytic obstruction develops, and it is this paralytic obstruction which is responsible for the symptoms which are present. As far as the general manifestations of toxæmia are concerned, there is nothing, then, to distinguish between a patient suffering from acute peritonitis and one suffering from primary acute obstruction.

The general appearance of this toxæmia bears a striking resemblance to that found in severe cases of gas-gangrene. The chief features which they have in common are, the rapid pulse, cyanosis, frequent presence of slight general icterus, and above all, the restlessness and pathologically acute consciousness, which may last to the very end. Sometimes a patient will remark brightly that he is feeling better, yet at that time his pulse may be imperceptible, and he may be dead in half an hour. At other times patients become peevish and petulant, complaining inordinately at trifles, such as the pain of a hypodermic injection, and giving an impression of irritable mental abnormality. These together give a symptom-complex which is found in no other toxæmia, such as typhoid, streptococcal cellulitis, or septicæmia, diphtheria or pneumonia, and the peculiarity suggests the possibility that in acute intestinal obstruction anaerobic organisms might be responsible for the toxæmia.

In acute intestinal obstruction the only obvious source of toxins is the contents of the obstructed intestine, and this investigation was begun by examining the intestinal contents of cases of acute obstruction and of peritonitis for evidence of abnormal proliferation of toxin-producing anaerobes.

NORMAL DISTRIBUTION OF TOXIN-PRODUCING ANAEROBES IN THE INTESTINES

It is first necessary to consider the normal distribution of anaerobes and the conditions in the human intestinal tract. Of these organisms the one which is most constantly found, and which is most numerous, is *Bacillus welchii*. It is an organism which is almost ubiquitous—in dust, soil, and milk—so that it is easy to account for its presence in the intestine. Whether it occurs as a passenger in food, or as part of the natural flora, is immaterial.

B. welchii is an organism which produces a very powerful toxin, and requires for growth and the production of toxin a medium which is anaerobic and is maintained on the alkaline side of neutral. The toxin is extremely labile and in acid medium is rapidly destroyed. Moreover, by its growth it produces a great deal of acid, so that the toxin is destroyed unless the reaction is maintained by "buffering" of the medium, or by the addition of alkali.

Herter[1] has shown that in the small intestine the conditions are anaerobic, while the reaction is alkaline to neutral in the lower part, and is kept so by the alkaline secretions. These conditions would appear to be ideal for the proliferation of *B. welchii* and the production of toxin, but in life the time during which food material is in this part of the intestine is normally extremely short. A barium meal usually passes through the small intestine in four hours and it is extremely rare to see any prolonged delay. When stagnation takes place in the small intestine, however, either as a result of organic or paralytic obstruction, proliferation of *B. welchii* and toxin formation might easily occur.

In the stomach the aerobic conditions and acid reaction would prevent the growth of *B. welchii* and the formation of toxin and, clinically, pyloric obstruction gives rise to no acute toxæmia.

Again, in the large intestine, the medium becomes rapidly acid, so that *B. welchii* would be outgrown by other organisms and its toxin destroyed. Actually, though there may be considerable growth of *B. welchii* in the cæcum, in the fæces it is frequently impossible to obtain *B. welchii* on culture. Here, also, clinically, it is a matter of common observation that constipation or obstruction of the large intestine causes no acute toxæmia until stagnation extends back into the small bowel. On this hypothesis, therefore, there should be a great proliferation of *B. welchii* in the small intestine of patients suffering from acute intestinal obstruction. As time goes on these organisms would be found higher and higher up the small intestine and eventually in the vomit.

The investigation was begun by examining the vomit and small intestine contents of cases of acute obstruction and peritonitis for evidence of proliferation of *B. welchii*. Films were made in a standardised manner, which gave a rough idea of the numbers of *B. welchii* present. It is not possible to enumerate individual anaerobic organisms on morphological appearances alone with certainty, so no attempt has been made to count them. Final identification of *B. welchii* depended upon cultural reactions and the results of mouse inoculation, using pure protective antisera for control. The results were as follows. In 20 specimens of vomit obtained from cases of peritonitis *B. welchii* were present in large numbers in 19. In 12 specimens of vomit obtained from cases of acute obstruction *B. welchii* were present in large numbers in 11. In six specimens of small intestine contents examined *B. welchii* were present in enormous numbers in each specimen. Some of the film preparations of vomit showed very large numbers of organisms morphologically resembling *B. welchii*, but in other films they were not so numerous. This did not appear to bear any relation to the gravity of the case, and probably depends upon dilution of the intestinal material in the stomach.

As controls, 12 test-meals and vomit from two cases of pyloric obstruction were examined in the same way. No organisms resembling *B. welchii* were seen on films, but once *B. welchii* was obtained on culture. I only obtained one specimen of normal small bowel contents and a film, made from the lower end of the ileum, showed a few organisms resembling *B. welchii*—but they had to be looked for. *B. welchii* were grown from this specimen on culture and also from higher up the intestine. This agrees with the results of other workers,[2] that *B. welchii* are found, but are not abundant, in the small intestine.

TESTS FOR TOXIN

From these observations it appears that there is a great proliferation of *B. welchii* in the small intestine in cases of acute obstruction and of late peritonitis. Proliferation of *B. welchii* does not, however, necessarily imply that toxin formation takes place. The organism may be abundant in the large intestine without any clinical toxæmia, and in vitro active growth may take place without the formation of demonstrable toxin. It would therefore be necessary to demonstrate the presence of the toxin in the contents of the small intestine from cases of acute obstruction or of peritonitis.

The technical difficulties of demonstrating a toxin as delicate as *B welchii* toxin in material such as intestinal contents are very great. The toxin is apt to be destroyed in the process of rendering the material bacteria-free. The only method which I found practicable was Berkefeld filtration in an ice-chest, in an atmosphere of hydrogen The bacteria-free fluid was then inoculated into mice intramuscularly, using antitoxic sera as controls

Attempts to demonstrate Welchii toxin in vomit were unsuccessful, except in one doubtful case, but the acid reaction in the stomach would account for destruction of any toxin which might be present.

With the small intestine contents experiments were more successful Material obtained from human cases of obstruction or peritonitis, and from dogs in which these conditions had been produced experimentally, was examined and the results are represented in Table I.

TABLE I

Source of intestinal contents	Duration	Unprotected mice		Protected mice	
		Total	Died	Total	Died
Peritonitis					
Human case	7 days	10	5	5	0
Dog 1	83 hrs	4	4	2	0
„ 2	65 hrs	6	6	2	0
„ 3	78 hrs	6	4	4	0
Obstruction					
Human Case 1	3 days	12	2	6	0
„ 2	4 days	10	2	10	0
Dog 1	56 hrs	8	7	4	0
„ 2	51 hrs	8	0	4	0
Totals		64	30	37	0

This experiment is definite evidence of the presence of toxin, but gives no indication of the original amount present A large proportion would be lost during filtration, besides the probability that destruction and absorption of toxin are taking place continuously during life

Material obtained from the large bowel from three cases of acute obstruction of the large intestine was also examined This material was acid in reaction and, though there were apparently large numbers of *B welchii* present, no toxin could be found In all, 66 mice were injected with the filtrate from this source without ill-effects This is in accordance with the absence of clinical toxæmia in cases of obstruction, when stagnation is confined to the large intestine The contents of the normal small intestine were examined in one case and found to be non-toxic

Thus there is evidence of enormous proliferation of *B welchii* and of the actual presence of the exotoxin of *B welchii* in small intestine contents of cases of acute obstruction It is of course possible, but unlikely, that the toxin, though present, might not be absorbed At the same time *B welchii* toxin was the only toxin lethal to mice of which any evidence could be found, and it is reasonable to assume that this is the toxin responsible for the clinical appearance of these cases, which is so similar to that of cases of gas-gangrene In addition to this, *B. welchii* toxin usually contains a very powerful hæmolysin, and anæmia and slight general icterus are well-known features of cases which have survived for some time Staining of the intima of the heart and great vessels as a result of intravascular hæmolysis is a well known finding in fatal cases of peritonitis Intimal staining is also not uncommon in fatal cases of acute intestinal obstruction; I have found it present in 9 out of 14 human cases and it was sometimes very marked

This hæmolytic staining is usually attributed to the presence of hæmolytic streptococci, though there may be no other evidence of their presence Had a streptococcal septicæmia been responsible, one would expect metastatic foci, and changes in the spleen, which were not present in these cases Of the five dogs in which obstruction or peritonitis had been produced experimentally hæmolytic staining was found in four cases, and in these dogs blood cultures, taken within a few hours of death, were negative in three cases In the fourth a variety of organisms were grown, probably a contamination I think therefore that in the absence of evidence of other known hæmolytic organisms, the presence of intravascular hæmolysis in cases where *B welchii* toxin has been demonstrated in the intestinal contents is very strongly evidence of the absorption of *B. welchii* toxin

The general histological changes produced by *B. welchii* toxin are not very characteristic Kettle has found fine fatty degeneration in the liver and heart muscle, and I have found such changes in cases of acute obstruction and peritonitis These appearances are in no way diagnostic of *B welchii* toxæmia, but the fatty degeneration of the cardiac muscle has a clinical importance which will be referred to later

THERAPEUTIC TEST.

In acute obstruction the only obvious source of toxin is the contents of the obstructed intestine In peritonitis, on the other hand, the infection in the peritoneal cavity may well give rise to considerable toxæmia, though it is only in those cases which develop "paralytic ileus" that the mortality is high and the characteristic toxæmia develops. It has, however, been suggested, as long ago as 1897 by Veillon and Zuber,[3] that in acute appendicitis it was *B welchii* which was responsible for the infection of the appendix, the peritonitis, and the consequent toxæmia. This depended upon the finding of *B welchii* in a large proportion of acutely inflamed appendices This observation has been confirmed and emphasised more recently by Weinberg,[4] and anti-gas-gangrene serum has been used in France for some years in severe cases of appendix peritonitis The results were summarised by D G Michel[5] in 1923, and a great improvement in mortality has been claimed On the other hand, in this country many observers agree that *B welchii* is only found in the immediate vicinity of a perforated appendix, and its presence results from contamination by bowel contents and is not usually the cause of either appendicitis or peritonitis Moreover, the characteristic toxæmia will develop when there is paralytic ileus, whatever the cause of the peritonitis, whether streptococcal, pneumococcal, or resulting from any other organism, when *B welchii* is not present in the peritoneal infection Obviously the presence of a few *B welchii* in the peritoneal infection cannot account for the whole toxæmia, though it may contribute a quota when present It is the intestinal contents which must be the greatest and most constant source of toxin At the same time, the successful use of anti-gas-gangrene serum containing *B welchii* antitoxin by the French surgeons corroborates the hypothesis put forward in this investigation, that the intestinal toxæmia resulting from stagnation of the small intestine contents is due to *B welchii*

I have at St Thomas's Hospital been trying the effects of *B welchii* antitoxin in cases of acute obstruction and of peritonitis with paralytic ileus for the last two and a half years With cases of peritonitis resulting from gastric or duodenal perforation, pneumococcal infection, or so-called primary streptococcal infections, the numbers were very small, and it is not possible to make any useful statistical comparison of the results of the use of antitoxin

For statistical comparison, cases of peritonitis resulting from acute appendicitis were selected, because · (1) a reasonably large number is available annually, (2) the mortality of the disease is very constant, (3) it is usually cases which develop paralytic ileus which are fatal, and the progress of the disease can be easily followed

Under modern conditions, thanks to the work of the pioneers in early operative treatment of cases of acute appendicitis, the majority of cases recover without ever developing serious intestinal paralysis, and in consequence no severe anaerobic toxæmia It was therefore decided only to administer *B welchii* antitoxin to those cases in which one could say the chances of survival were 50 per cent or worse This included. (1) moribund cases of severe "general peritonitis"; (2) streptococcal peritonitis, unlocalised, in children under 12 years old, (3) cases which, after appendicectomy, continued to show signs of advance of the disease by rising pulse-rate, abdominal distension, and toxæmia

To increase the numbers, Mr P H Mitchiner (assistant surgeon), Mr A C Halliwell (resident assistant surgeon), and Mr C V Patrick (surgical registrar) consented to administer antitoxin to suitable cases operated upon by themselves The series consisted of 256 consecutive and unselected cases Eighteen of the most severe cases, including ten children under 12 years old, were treated with *B welchii* antitoxin There were three deaths in the series One death was due to cardiac failure in a woman of 68, 31 days after operation, when the abdominal condition was completely recovered One death was thought to be due to pulmonary thrombosis or embolism. No post-mortem was obtained One must be regarded as a failure, the patient dying with paralytic ileus in spite of the administration of *B. welchii* antitoxin (Table II)

Test series mortality	1 17 per cent (256 cases)
Normal mortality, 1925	6 3 per cent (111 cases)

This showed a considerable reduction of mortality With the exception of the use of antitoxic serum, these cases were treated on the usual lines in vogue at St Thomas's Hospital Cases seen in the first 48 hours of the disease were operated upon and appendicectomy performed Except in young children, cases seen after more than 48 hours from the onset of the attack were not operated upon unless there were signs of spreading peritonitis or of an abscess which required drainage In young children, on account of the usual failure to localise the infection, appendicectomy was always carried out as soon as possible Drainage, except of the abdominal wall, was not employed unless there was a definite abscess cavity, or doubt about the suture line, or if the presence of concretions in the abdomen was suspected

In the therapeutic test of *B welchii* antitoxin in cases of acute obstruction classification for comparative purposes is more difficult

It is very difficult to exclude errors due to individual difference of opinion as to what constitutes acute obstruction For comparison I have taken as the control series figures from a paper published by Mr. C M Page[6] giving the mortality at St Thomas's Hospital for the years 1919 to 1923 In this series, and in the series used for the therapeutic test of *B welchii* antitoxin, the classification was done by Mr C V Patrick, surgical registrar to the hospital Cases of obstruction due to malignant disease, though arising primarily in the large bowel, are included when there were acute symptoms, for the reason suggested before, that the acute symptoms and toxæmia are an indication that stagnation had extended back into the small intestine Idiopathic intussusception in infants is excluded, because manifestations of acute obstruction do not usually develop Mesenteric thrombosis is excluded, because it cannot be relieved surgically

The selection of cases for the administration of antitoxin is also difficult, because it is impossible to predict how any individual case will behave On two occasions a case which appeared perfectly fit before operation took a sudden turn for the bad after relief of the obstruction and died before antitoxin could be administered. Excluding these two cases, the test series consists of 54 consecutive cases, as shown in Table III

TABLE III

Cause of obstruction	Control series		Test series	
	B welchii antitoxin			
	Not used		Used

Large intestine	1	1	2	0
Inguinal hernia	44	6	11	0
Femoral „	66	11	13	1
Umbilical „	22	7	3	0
Totals	214	53	54	5
Mortality	24 8%		9 3%	

Of these 54 cases, 19 of the most severe were treated with *B welchii* antitoxin In other respects all cases were treated on the usual surgical lines Of the five deaths, one was due to streptococcal septicæmia from a prick, nothing to do with his obstruction, one was due to post-operative gangrene of gut; three were extreme cases and failed to react

In cases of acute obstruction of the type discussed, the mortality is normally so high, between 20 and 30 per cent, that the use of antitoxic serum would always be justifiable Further, it is not uncommon to see cases which, after most successful operative relief, suddenly collapse unexpectedly This may be due to the sudden flooding of the circulation with a lethal dose of toxin by the very act of relief of the strangulated intestine This might occur through the restoration of the circulation to the damaged area permitting very rapid absorption of toxin, or possibly by rapid absorption of toxin by the normal mucous membrane distal to the obstruction after its relief The only way to control this danger would be prophylactic administration of antitoxin intravenously before operation, if necessary on the table This was not done in the series I have reported, but I have come to the conclusion that, in cases of acute obstruction, prophylactic administration of the *B welchii* antitoxin should always be employed when there are signs of involvement of the small intestine

IMPRESSIONS AS REGARDS THERAPEUTIC VALUE OF *B. welchii* ANTITOXIN IN OBSTRUCTION AND IN PERITONITIS

In cases of appendix peritonitis which showed the characteristic toxæmia associated with "ileus," the effect of *B welchii* antitoxin was often very striking. Restlessness was greatly diminished or abolished, and the look of acute consciousness disappeared, so that patients slept easily; cyanosis, when present, disappeared, and in one case a definite icteric tinge faded rapidly The pulse-rate usually began to fall after the administration of serum, and the quality of the pulse improved Abdominal distension often disappeared within a few hours of the administration of antitoxin and the patient, after complaining of "wind," began to evacuate the bowels spontaneously Even in severe cases the bowels usually began to act spontaneously, in spite of previous failure of enemata and pituitary though distension might not completely subside until convalescence was well established

In cases of acute obstruction similar effects were observed, but improvement usually follows so rapidly on successful operative relief that it is only by regarding the series as a whole that the effect of the antitoxin can be assessed

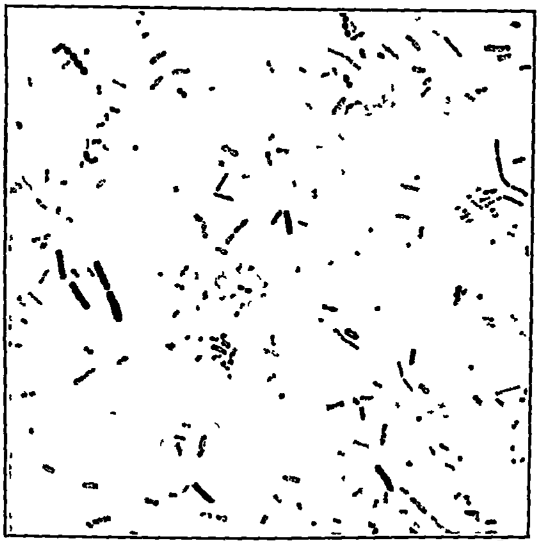
As regards the actual mortality-rates, each series appears to show a very definite improvement The series, however, are not sufficiently large for very positive deductions In diseases of this severity there must inevitably be a certain number of deaths, however perfect the treatment employed, and I think the figures obtained are surprisingly, and perhaps deceptively, good

I have not made any control series with the use of normal horse serum, on the assumption that this has been adequately tested in the *B coli communis* serum, which is seldom used now

DOSAGE AND INDICATIONS FOR TREATMENT

It is not suggested that the use of *B welchii* antitoxin is in any way alternative to the recognised surgical treatment of intestinal obstruction and of peritonitis It is put forward as a means of combating toxæmia consequent upon stagnation of the contents of the small intestine, which cannot otherwise be dealt with successfully In cases of peritonitis, intestinal paralysis and consequent stagnation as a rule develop gradually, and it is not difficult to select those cases in which the administration of antitoxin is justifiable

FIG 1



Standard film of vomit from a case of peritonitis

In view of these considerations, it is suggested that *B welchii* antitoxin should be given to all cases of peritonitis which shows signs of intestinal paralysis and toxæmia, as manifested by severe or progressive abdominal distension, increasing pulse-rate, restlessness, repeated vomiting, particularly if brown or offensive, especially if these signs continue after surgical treatment has been carried out Fatty degeneration of the cardiac muscle has been shown to occur, and it is essential that this should not progress too far to be recoverable

The effect of antitoxic serum is to neutralise toxin after its absorption from the intestine It is important, therefore, to realise, particularly in paralytic obstruction due to peritonitis, when the peritonitis which is the cause of the paralysis is still operative, that a clinical improvement is not an indication for stopping the administration of serum An adequate supply of antitoxin must be continued until the small bowel is emptying itself regularly and effectively By this means a patient may be given time to overcome the peritoneal suppuration, and the peritoneum has extraordinary powers of recovery.

In the therapeutic use of antisera it is essential that large doses should be employed The disadvantages such as sensitisation are not for practical purposes increased by the size of the dose, and young children require as much as adults

Many people still appear to regard the use of horse serum in human patients as a very dangerous procedure This it certainly is not An enormous number of patients every year are now given horse serum, both in this country and abroad for other diseases, such as diphtheria, tetanus and, now, scarlet fever, and fatalities from the serum must be so rare as to be negligible The dangers of administering serum cannot be compared with the dangers of a condition like acute obstruction or peritonitis with ileus Anaphylaxis is a phenomenon found in guinea pigs and mice and is excessively rare in human beings Further, as an extra precaution, an intradermic test can always be made and if necessary desensitisation can be quite easily and rapidly carried out Serum rashes occurred in a few of the patients of this series, but was never the cause of any anxiety.

The serum used was anti-gas-gangrene serum, prepared by Burroughs, Wellcome and Co, Series G155, for therapeutic use I found no indication for the inclusion of vibrion septique antitoxin, but this was the only reliable serum available containing *B welchii* antitoxin It is hoped that a pure *B welchii* antitoxin of higher titre will shortly be available The initial dose of serum should be at east 80 c cm intramuscularly In extreme cases a further 40 c cm should be given intravenously on the table After the initial dose 40-80 c cm should be given intramuscularly daily until the bowels are evacuating spontaneously and effectively The most difficult cases are those in which matting of the intestine occurs, producing obstruction which may be organic The use of antitoxin must not be allowed to prejudice the question of operative relief of obstruction due to matting of the intestines, as a result of peritonitis In cases of acute obstruction, where there is reason to suspect small bowel involvement, for the reasons already discussed, it is suggested that antitoxin should always be given prophylactically An initial dose of 40 c cm should be given intravenously before operation, with a further 40 c cm intramuscularly After operation further doses of 40-80 c cm should be given daily until the bowels are acting regularly.

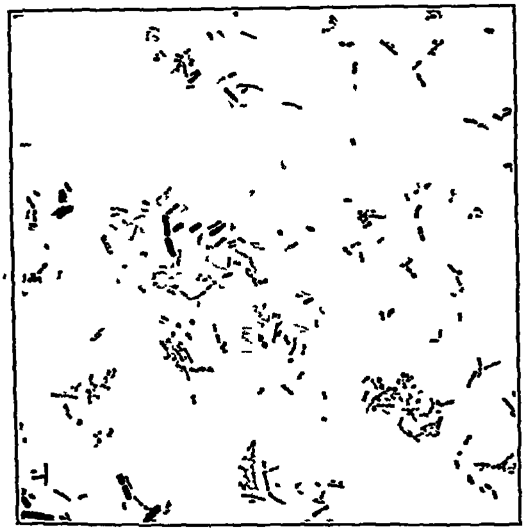
I have in this series sometimes used smaller doses, but the series was experimental, and for general purposes I am convinced that the best results can only be obtained by the use of larger amounts

DISCUSSION

This investigation was begun on the hypothesis that the toxæmia in cases of acute intestinal obstruction, whether organic or paralytic, was due in part at least to the absorption of *B welchii* toxin from the stagnant contents of the small intestine It is not asserted that this is the only toxin present, but it was the only toxin of which evidence was found by the most delicate tests available If it is true, the hypothesis offers a simple solution for many unexplained problems

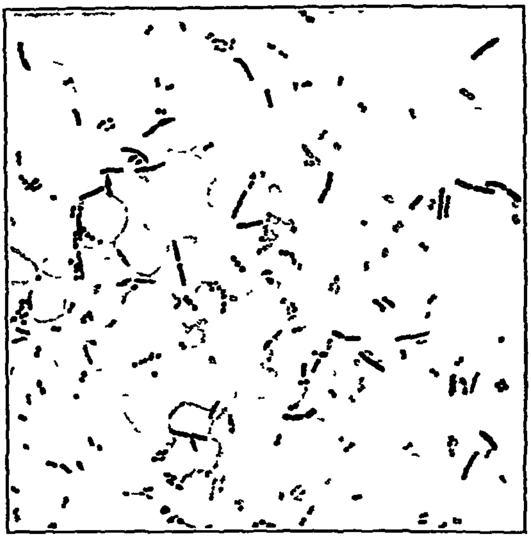
One of the most difficult and dangerous complications of acute intestinal obstruction or of peritonitis is paralysis of the intestine Apart from the suggestions arising from this investigation, the treatment of "ileus" has always been unsatisfactory Many procedures have been advocated, such as doses of pituitary or eserine, jejunostomy, ileostomy, and ileocolostomy, but all require for their success that the bowel should still be able to contract If the intestine is really paralysed, pituitary and eserine fail to secure evacuation, while they put a great strain on the heart, which is already damaged by the toxæmia Jejunostomy, ileostomy, and ileocolostomy have all the disadvantages of operative procedures carried out on patients who are already gravely ill and, if the intestine is really paralysed, will only secure evacuation of the loop into which an opening has been made The amount of material obtained by drainage is often disappointing Of the six cases in which ileostomy or jejunostomy was performed for obstruction or peritonitis, I have only three times been able to obtain sufficient material for filtration In these cases *B welchii* antitoxin was being administered in large amounts

FIG 2



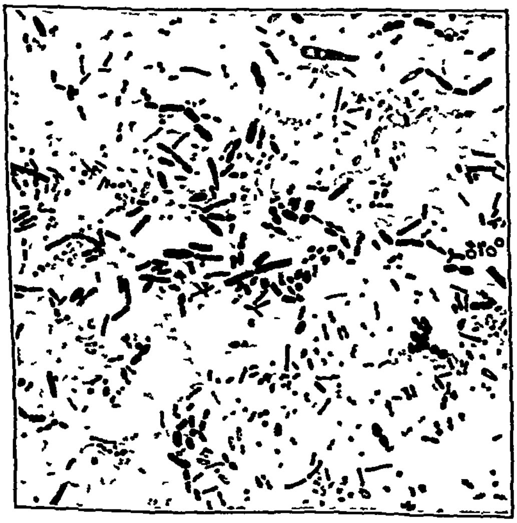
Standard film of vomit from a case of obstruction

FIG. 3.



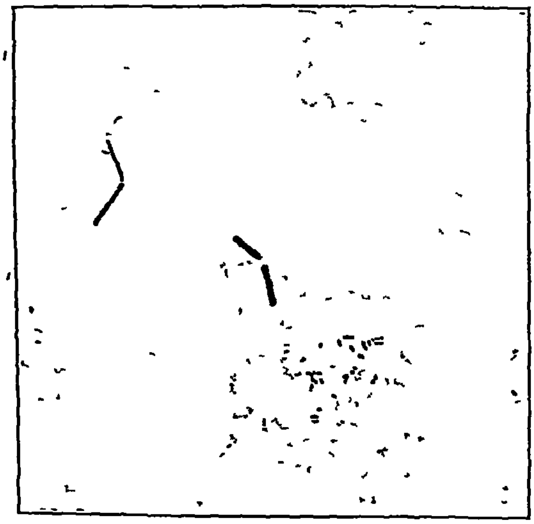
Standard film of small intestine contents from a case of peritonitis

FIG 4



Standard film of small intestine contents from a case of obstruction

FIG 5



Standard film of contents of normal terminal ileum A selected field showing organisms resembling *B welchii*

Now the toxin of *B welchii* has a special affinity for muscular tissue and it may well be that this paralysis of the intestine is in part due to an absorption from the intestinal contents of *B welchii* toxin, to which the muscle wall is exposed in its greatest concentration Thus the administration of antitoxin besides combating the general toxæmia, may contribute towards the recovery of the intestinal muscle so that the toxic intestinal contents can be evacuated and absorption of toxin be brought to an end It was observed repeatedly, during the clinical trial that distension disappeared and the bowels began to act freely after the administration of serum As this coincided with clinical improvement, it cannot be definitely attributed to the direct action of the antitoxin on the intestinal muscle

The very high mortality of obstruction of the small intestine by bands and adhesions coincides with ideal conditions for the development of *B welchii* toxin in the contents of the small intestine from the very onset of the disease The complete absence of toxæmia in patients suffering from absolute constipation, even for weeks, or of chronic obstruction of the large intestine, coincides with the unsuitable conditions in the large intestine for the development of *B welchii* toxin Again, in pyloric obstruction the unsuitable acid medium explains the entire absence of toxæmia

Again, the difference between patients suffering from a peritoneal infection, as contrasted with a pleural infection, even of the same organism, has always been the subject of speculation This difference may on this hypothesis be explained on the assumption that in peritoneal infections the clinical picture will result from the absorption of *B. welchii* toxin from the stagnant contents of paralysed small intestine The gravity of the toxæmia will be in proportion to the extent of small intestine affected, and will be much greater in diffuse infections than in cases where there is a localised abscess This is in complete accord with clinical experience.

Conclusions

To recapitulate the evidence on which the hypothesis rests 1 There is clinical resemblance of the toxæmia in acute obstruction and peritonitis with ileus and the toxæmia of gas-gangrene 2. There is evidence of immense proliferation of *B welchii* in the contents of the small intestine of patients with acute obstruction and peritonitis 3 There is evidence of the presence of the actual exotoxin of *B welchii* in the contents of the small intestine of cases of acute obstruction and peritonitis, and in the intestines of dogs in which these conditions had been produced experimentally 4 There is evidence compatible with the absorption of *B welchii* toxin, from the clinical aspect of cases, from the occurrence of intravascular hæmolysis, and from microscopical changes in the heart and liver of fatal cases 5. The hypothesis is corroborated by the results of a therapeutic test of the use of *B welchii* antitoxin in cases of acute obstruction and of peritonitis

In conclusion, I believe that these experiments are the first to indicate the presence of a true bacterial toxin of intestinal origin, its nature, and the conditions of its development. By good luck, there is also a means to hand by which it can be combated The hypothesis offers a simple explanation for many problems Therapeutically, if subsequent results are as encouraging, it is important, because of the large number and high mortality of cases in which acute obstruction may occur It has not been possible to produce absolute proof of the hypothesis as a whole The nature of the problem and technical difficulties make absolute proof impossible, even with very much greater numbers of observations that I have been able to make, greater reliance is therefore placed on the fact that evidence has been found in support of the probable truth of the original assumption by many lines of approach

Full details of the experiments are recorded in a paper contributed to the *British Journal of Surgery*, October, 1926 The work was begun in collaboration with Dr. S C Dyke, now pathologist to the Wolverhampton Hospital It could never have been carried out without the generous help of Dr R A O'Brien and Miss Muriel Robertson

The investigation was carried out at the Clinical Surgical Unit, St Thomas's Hospital, where Sir Cuthbert Wallace and Mr B C Maybury have helped throughout, and Prof L S Dudgeon, during the later stages, with advice and suggestions

Bakers' Dermatitis and Compensation—At Southport County Court on April 7th a baker claimed compensation under the Workmen's Compensation Act from his former employers for bakers' itch contracted in the course of his employment Although he had now recovered it was submitted that he was a derelict on account of the state of the labour market, if he resumed work as a baker the disease was likely to recur The respondents contended that although the man was entitled to compensation, it was strictly limited Judge Thomas said he thought the applicant should return to work as a baker and granted compensation at the rate of £1 3*s* a week for 13 weeks He also made a suspensory order allowing him to claim again if necessary.

A FILTRABLE ENDOTHELIOMA OF THE FOWL.

By A M. BEGG, M.B, Ch.B.N.Z.

(From the Laboratories of the Imperial Cancer Research Fund)

The new growth which forms the subject of the present communication was discovered on post mortem examination of a White Leghorn hen which died on Nov 2nd, 1925 A large globular tumour of the ovarian region was regarded as the primary growth, and the whole peritoneal cavity and the solid and hollow viscera were studded with nodules of growth The metastases were similar to the primary growth in naked-eye appearance, being soft white healthy masses, the larger of which, especially in the liver, generally had a hæmorrhagic area in the centre Microscopically the nodules presented an indefinite alveolar arrangement of large cells irregular in shape The nuclei were large and vesicular, most of the chromatin being collected in a large single nucleolus The protoplasm showed a central finely granular area around the centrosomes and a peripheral coarsely granular zone Necrotic areas of varying extent were frequent and around them the cells had coalesced to multinucleate giant cells It was only after an extended study of the propagated tumours that the conclusion was reached that the parenchyma of the neoplasm was derived from endothelium, and the provisional descriptive label of *endothelioma* has been adopted The histological findings are reserved for a future communication

1 *Propagation by Cellular Grafts*

Seven young chicks were inoculated with grafts of 0 02–0 03 gr in the right and left pectoral muscles On the right the grafts were taken from the large (primary) growth, on the left from a liver metastasis The result of this primary transplantation is shown in the chart (Fig. 1)

Only one of the grafts failed to grow, that on the right side of chick No 6, killed 49 days after inoculation Transplantation of grafts has now been carried on for 20 generations, at an average interval of 27 days, fluctuating between 10–12 days and 55 days Two periods of depression, with slow growth and occasional absorption of the tumours, have been passed through, and have again given place to a phase of rapid growth

In the majority of the birds inoculated metastases have been found, most commonly in the liver and spleen The lungs have only occasionally presented macroscopic secondaries The kidneys, subcutaneous tissues, abdominal wall, and lymph nodes are occasionally involved, and widespread dissemination has frequently been observed in animals successfully inoculated with cell-free extracts An interesting instance of metastasis formation occurred in a bird of the third transplantation It had been lame for some days and was killed 55 days after inoculation The inoculation tumours in the breast-muscles were small, but on opening the abdomen extensive metastases were found in the liver and lungs A nodule 1 5 cm in diameter occupied the lower pole of the left kidney and the nerves of the left leg passed through, and were pressed upon by the growth, thus accounting for the lameness observed during life As in experiments with the Rous fowl sarcoma it is not unusual to find the association of extensive metastases with a small inoculation tumour—as in the above example, or, conversely, a large tumour at the site of transplantation and small or no metastases

Although the original tumour occurred in a White Leghorn hen, no racial restriction has been observed in transplantation, all races of domestic fowls being equally susceptible In this respect the present growth agrees with Rous's osteo-chondro-sarcoma

No 7, which exhibited the same catholicity (Tytler, 1913 [1])

2 *Propagation with Dried Material*

A bird with a large tumour, resulting from an inoculation of filtered incubated tumour, was killed, and the tumour removed aseptically It was minced finely and spread in a thin layer in a Petri dish, which was placed in a desiccator with phosphorus pentoxide The desiccator was evacuated and placed in the ice-safe Three days later the dried scales were removed and ground in a mortar with a small amount of sterile diatomaceous earth Normal salt solution was added and mixed to the consistence of a thick paste A chick received 0 5 c cm of this paste in the pectoral muscle of the right side (28/5/26) A large tumour (5 × 4 cm) resulted and the bird was killed 24 days later Multiple miliary metastases were found in the liver and a large nodule in the spleen A graft from the pectoral tumour was inoculated into a young bird which had to be killed 14 days later, the tumour having reached a size of 4 × 3 cm. Metastases were found only in the right lung

Another experiment similar to that in Fig 2 Chick No 6 was a Rhode Island and had very widespread metastases Filtrate Expt No 2, 11/5/1926 , 6 chicks inoculated in right pectoral muscle with 0 5 c cm Chamberland L 1 filtrate of a 23-hour culture, to which emulsion of chick embryo had been added

3 *Propagation by Filtered Material*

(*a*) *Direct filtrate* —A fowl with a large tumour resulting from the inoculation of filtered incubated material 42 days previously was killed on 22/6/26 The tumour was removed aseptically, and 2 g were taken and ground with sand To this ground-up material 80 c cm of Locke solution was added The fluid was clarified by filtration through sand and paper pulp, and the resulting clear fluid passed through a Chamberland L 1 filter candle The filtrate was mixed with the minced tissues of an 11-day chick embryo and the resulting emulsion inoculated into three chicks in doses of 0 5 c cm Two died early The third chick was killed 24 days later. A tumour, 5 × 2 5 cm , was found at the site of inoculation Metastases were present in the liver, spleen, lungs, intestines, ureter, and cervical glands

A similar experiment (30/6/26) in which two chicks were inoculated with 0 5 c cm of filtrate and embryo emulsion gave a similar result One chick was negative, the other died 25 days after inoculation with a large tumour (5 × 2 5 cm) and metastases in the spleen and cervical glands

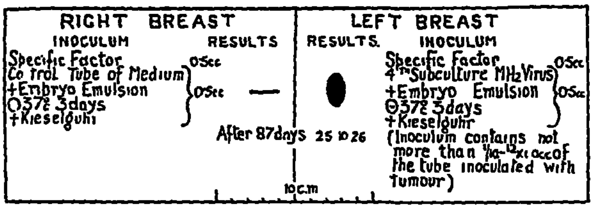
(*b*) *Filtration of broth “ cultures ”*—The polymorphism of the cells in the primary tumour and in several of the earlier propagated growths led us, erroneously, to regard this neoplasm as embryomatous (or at least mixed) in character, and in consequence an emulsion of embryonic cells was added to the inoculum in most of the experiments made with filtrates This was done in order to give opportunity for infection of a variety of tissues Later experiments and more extended histological study have shown this addition to be unnecessary

Fragments of tumours, removed aseptically, were incubated anaerobically in two tubes of rabbit serum KCl broth at 35° C These incubations of tumour in broth or serum broth are, for convenience, referred to as “ cultures ” Twenty-two hours later the supernatant fluid was carefully pipetted off and filtered through a Chamberland L 1 candle The filtrates were added to an emulsion, finely minced of chick embryo and five Rhode Island chicks each received 0 5 c cm into the muscles of the right pectoral region The result of the experiment is shown in Fig 2 Three out of the five birds were successfully infected Two repetitions of this experiment have been carried out The result of the first of these (Filtrate Expt No 2) is shown in Fig 3 (It is of interest to note that chick No 6 of this experiment, killed 30 days after inoculation, was a Rhode Island bird, the primary tumour having occurred in a White Leghorn This neoplasm does not show the same strict racial predilection which is so well seen in the case of Rous's No 1 sarcoma but, like Rous's osteo-chondro-sarcoma No 7, it grows equally well in all the races of domestic fowl which have been tested) In the third experiment of this series (26/5/26) three chicks only were inoculated One died six days after inoculation The embryonic tissues inoculated with the filtrate were still proliferating freely, so that it is impossible to decide whether infection had occurred The second was killed 19 days after inoculation There was a large primary growth, metastases in the liver, and enlarged cervical glands The third died 118 days after inoculation with a large pectoral tumour, and metastases in liver, spleen, œsophagus, and pancreas

In each of these three experiments the tumour material used arose from a graft of living cells It was of interest to determine whether the tumours so produced could themselves give an active filtrate after incubation The tumour from bird No 1 of Filtrate Expt No 2 (Fig 3) was removed aseptically, and fragments placed in three tubes of broth The tubes were incubated anaerobically as before Three White Leghorn chicks were inoculated with the filtered broth from these tubes with added embryo emulsion All three were positive, dying 16, 17, and 26 days after inoculation The experiment was repeated with the tumour from bird No 6 of the same experiment (Fig 3), except that the tumour was incubated in serum broth Two White Leghorn chicks were inoculated as before Both developed tumours and died 17 and 22 days respectively after inoculation

(c) *Propagation with filtered fluid alone (no embryonic cells added)*—Three separate attempts were made to infect developing chick embryos with filtered broth "culture," but all were unsuccessful The attempt was then made to produce the tumour in young chicks with filtered broth cultures Three chicks were inoculated (26/5/26) with 0 5 c cm filtered broth culture to which a small quantity of kieselguhr was added One died after 3 days and another after 43 days and were negative The third was killed 26 days after inoculation, it had a large tumour in the pectoral muscles (5 × 2 5 cm) and numerous large metastases in the liver Smaller secondary growths were found in the spleen, pancreas, and adrenal

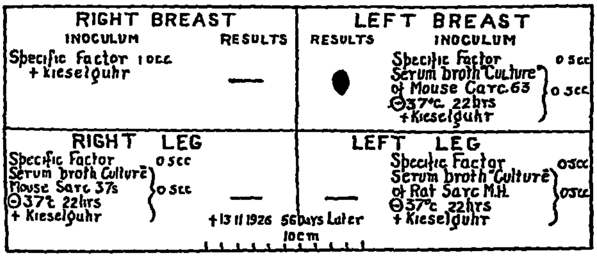
FIG 4.



Acriflavine inactivation Expt No 14 (vide table) 30/7/1926 Two chicks inoculated, one died five days later Showing inertness of filtrate from tumour incubated in acriflavine broth (1 3500) alone (r breast), and restoration of activity *by addition of fourth subculture of* MH_2 *virus (l breast)*

The experiment was repeated (3/6/26), 1 c cm of filtrate and kieselguhr being injected into three White Leghorn chicks All three were positive, dying 18, 21, and 26 days respectively after inoculation Metastases were present in the first two, but not in the bird dying at 26 days, although this bore the largest tumour (5 × 3 5 cm).

FIG 5



Acriflavine inactivation Expt No 15 (vide table) 18/9/1926 Attempted substitution of mammalian viruses Two chicks inoculated, one alive and negative at all sites, 6/4/1927 Successful reactivation of acriflavine broth filtrate of MH_2 (r breast) by "culture" of mouse carc (l breast) and failure with mouse and rat sarcoma "cultures" (r and l leg)

4 *Analysis of Transmission without Living Cells*

It is clear from the foregoing experiments that this propagable endothelioma belongs to the same group of tumours of the fowl as the three Rous sarcomata, 1,[2 3] 7,[1 4] and 18,[5] Fujinami's sarcoma,[6] and the tumours described by Teutschlander,[7] and others At the present time opinions are divided as to the true nature of these tumours of the fowl and in particular as to their relation to the malignant neoplasms of mammals A widely entertained opinion is that these fowl neoplasms are a peculiar group of virus infections of connective tissues, comparable with, and most closely related to, the epithelial overgrowth of fowl and pigeon-pox Their similarity to mammalian sarcomata is on this view superficial and deceptive Those who hold the contrary opinion that, viz , these neoplasms are true sarcomata, essentially the same ætiologically and biologically as the corresponding new growths of mammals, differ among themselves, some holding that a living infectious agent (virus) need not be postulated, pinning their faith to peculiarities of enzyme action (Carrel, Murphy [8]) and others While many workers have affirmed a belief in the microbic causation of cancer, the only coherent statement of the virus nature of these and all other malignant new growths is that of Gye [9] His view, based on a study of Rous sarcoma No 1, puts the tissue and racial specificity of these conditions in the forefront of his argument The virus he regards as relatively non-specific and common to most of the new growths, carcinomata as well as sarcomata, of birds and mammals The tissue and racial restrictions in transmission without living cells are believed by Gye to depend on the presence of a chemical substance derived from the host, the "specific factor" This of itself, without the virus, cannot give rise to a tumour, *without its concurrence the virus is innocuous*

The following experiments were undertaken to test the validity of Gye's conception on the related but distinctive material, presented *by this propagable* endothelioma The technique followed is that described by Gye (1925,[9] 1926[10]) and throughout I have had the advantage of Gye's personal advice and criticism The responsibility for the results and the conclusions drawn from them is mine. The experiments are being continued, and the present instalment should be regarded merely as a contribution to the *controversy which has followed* the publication of Gye's papers The work is technically exacting and time-consuming, and it is not surprising that differences of fact and interpretation still exist

HCN inactivation Exp No 1 HCN (vide table) 21/6/1926 Two chicks inoculated, one negative at all sites Result after 47 days of inoculation of single factors ("specific factor" r breast, "virus" r leg) and combined factors (l breast)

Gye's original method [9] of obtaining the "specific factor" free from virus, by the action of chloroform, has failed completely with the Mill Hill endothelioma The two alternative methods of rendering the virus inactive, leaving the "specific factor" in play, by the action of acriflavine and by hydrocyanic acid (Gye, 1926 [10]) have been more successful Heating active fluids to 55° C for 15 minutes gives a product which can restore the tumour-producing power of the fluid which has been rendered inert by acriflavine or hydrocyanic acid Heat-inactivated fluids of this kind are used in the following experiments to supply the virus with two exceptions—acriflavine Expts 14 and 15 (Figs 4 and 5) The end-points of these inactivations are not sharp, and it is only by the result of the animal experiment that it can be inferred that the active substances have been reduced below the threshold concentrations When the additional difficulties introduced by variations in tumour virulence and individual susceptibility of the chicks are borne in mind, it is not surprising that completely convincing demonstration of the dual nature of non-cellular transmission has not yet been achieved, but the results so far obtained are in harmony with this view

The accompanying table gives the results of all the experiments which have been undertaken to analyse the mechanism of non-cellular transmission of this tumour

A = Chloroform. B = Acriflavine C = Hydrocyanic acid

In the first series in which inactivation of the virus by chloroform was employed the control inoculations with single inactivated fluids were made into separate birds from those receiving the mixtures containing both factors In the later experiments (with the one exception of Expt 13 acriflavine) separate sites of the same bird were used for control (single factor) and combined (both factors) inoculations The change over is indicated in the table by *∿∿∿∿. This alteration was rendered necessary by the errors introduced by individual variations in susceptibility of the birds The drawback to this form of the experiments is the possibility of diffusion of the virus to the rest of the body, so that tumours arise apparently at the point where "specific factor" alone had been introduced A disposition of the experiment which will evade these difficulties has not yet been devised As will be seen from the table, the results of the chloroform inactivation experiments are inconclusive, in some all the birds are negative, in others tumours have arisen from the injection of presumably single factors.

Acriflavine and Hydrocyanic Acid Inactivation

The details of the preparation of "virus" and "specific factor" relatively free from each other in the remaining experiments is as follows —

(*a*) Elimination of "specific factor" Preparation of inactivated "culture" (virus suspension) The supernatant fluid of an anaerobic "culture" of the tumour in broth (22 hours) is carefully removed and heated for 15 minutes at 55° C. to destroy the specific factor

(*b*) Destruction or diminution of virus by acriflavine, with preservation of "specific factor." To a tube of serum broth acriflavine is added in amount sufficient to give a concentration of acriflavine 1 : 3500. 0 5 g of minced tumour is introduced and the tube incubated anaerobically for 22 hours at 37° C The supernatant fluid is taken and spun for 15 minutes at a high speed, and the upper clear layer carefully pipetted off—"specific factor" (acriflavine)

(*c*) Destruction or diminution of virus by hydrocyanic acid 0 5 gr tumour emulsion is incubated anaerobically at 37° C for 3 days in a tube of serum broth The reaction of the supernatant fluid at the end of this time had risen to pH 6 0 To 4 9 c cm of the undisturbed supernatant fluid is added 0 1 c cm of 1 per cent hydrocyanic acid, giving a concentration of HCN 1 5000 This is incubated aerobically for 30 minutes at 36° C, and the hydrocyanic acid then pumped off under a Geryk pump—"specific factor" (HCN)

Summary

The biology of a tumour of the domestic fowl with the structure of an endothelioma is described It can be propagated by cellular grafts, by dried material, and by filtrates of tumour emulsion direct, or after incubation anaerobically, in broth culture media An attempt has been made to test the validity of Gye's conception of the dual nature of non-cellular transmission for this tumour, and the results are in harmony with his views

THE EXPERIMENTAL PRODUCTION OF A NEW TYPE OF GOITRE UNRELATED IN ITS ORIGIN TO IODINE *

BY ROBERT McCARRISON, C I E, M D R U I, D Sc BELF, F R C P LOND.
LIEUT-COL, I M S, DIRECTOR, DEFICIENCY DISEASES INQUIRY, PASTEUR INSTITUTE, COONOOR, S INDIA

THE goitres hitherto produced by me under experimental conditions in animals [1] (pigeons, rats, and goats) have been of three types · the hypertrophic, the hyperplastic, and the colloid The first may arise in animals living under unhygienic conditions of life in iodine-poor localities, it arises also in animals receiving massive doses of fæcal bacteria in admixture with their food, congenital goitre and cretinism being thereby produced in their offspring The second may arise in animals receiving an excess of fats or of fatty acids in an otherwise well-balanced diet [2] The third has not been produced in typical form as seen in man, but a condition simulating it in pathological features has resulted in animals from the excessive ingestion of lime in an otherwise well-balanced food [3] With the possible exception of those caused by the administration of cultures of fæcal bacteria the goitres produced in these ways are preventable, by increasing the intake of iodine proportionately to the unhygienic conditions of life of the animals, or to the excess of fats or of lime in their food The present paper deals with the experimental production of a variety of goitre which conforms to none of these types, which has distinctive ætiological and pathological features, and is unrelated in its origin to the iodine ingested Its histological features are those of an intense secretory hypertrophy approaching that seen in primary Graves's disease

In view of the comparatively wide prevalence of "simple goitre" amongst white-flour-eating peoples and of the prominence which has of late years been given to iodine deficiency as its sole cause, and to iodine prophylaxis as the only means of its prevention, it was thought desirable to ascertain whether diets into which white flour entered largely, and from which green vegetables and fruit were excluded, could give rise to, or favour the development of, "goitre" in animals receiving iodine in adequate amounts and living under conditions of the strictest hygiene

Details of the Experiments

Sixteen groups of young rats from non-goitrous stock, six animals in each group, were selected for this work, males and females being as far as possible equally distributed in each group and the age of the animals being approximately the same (30 to 60 days) Their initial weights ranged from 30 to 67 g Each animal was confined in a separate cage so constructed as to render hygienic conditions of life as perfect as possible The cages were provided with netted-wire bottoms of fine mesh through which the excreta fell into zinc trays below During feeding time clean trays were passed into slots above the netted-wire bottoms of the cages so as to prevent loss of food, at the same time attendants went from cage to cage removing any excreta passed The cages were washed with antiseptic lotion daily and were sterilised in boiling water at regular intervals in a specially constructed apparatus (These precautions are absolutely essential in all experimental work on goitre in order that the factor of dirt may be excluded, this factor being of itself prone to cause thyroid changes, sometimes amounting to actual goitre, especially if the iodine intake of the animals be low [1, 5, 6]) At night the animals were bedded in sterilised cotton waste Each was given a known quantity of its particular diet daily, the balance not eaten being weighed and the daily food consumption by each animal recorded Distilled water was provided for drinking and washing purposes Each animal was weighed weekly and the weights charted. Clinical notes of any symptoms shown by them were kept, and a complete post-mortem examination of each was made at the end of the experiment so as to ascertain the cause of death In animals dying before the end of the experiment post-mortem examination was made as soon as possible after death in order to limit the autolytic changes to which the thyroid gland is so liable In none of the experimental animals was post-mortem examination delayed for longer than 12 hours; in very few for so long The animals surviving to the end of the experiment were killed and their thyroids removed and fixed immediately The diagnosis of "goitre" was made on macroscopical characters and subsequently confirmed microscopically A number of non-goitrous thyroids were also examined for purposes of comparison with the goitrous, and in order to detect the earliest signs of the gland's departure from normal

The Experimental Diets

The materials used in the preparation of the experimental diets were American white flour, purified starch, olive oil, "meat residue" and "salt mixture" The "salt mixture" was made up as follows Calcium lactate, 39 g, calcium phosphate, 16 2 g, potassium phosphate, 28 62 g., iron citrate, 3 54 g, sodium chloride, 5 19 g, magnesium sulphate, 7 98 g; sodium phosphate, 10 41 g; and potassium iodide, 0 5 g (McCollum and Davies).[7] The "meat residue" was prepared by a method described elsewhere [8] The percentage composition of the diets is given in the table together with the number of cases of goitre resulting from the different diets

Table showing the Percentage Composition of the Experimental Diets and the Incidence of Goitre

* I and XVI are control diets

Influence of the Experimental Diets in Causing Goitre

There were 25 cases of thyroid enlargement among the 96 animals a case-incidence of 26 per cent The various diets range themselves into three classes according to their influence in causing goitre —

(*a*) Those in which the white flour content is greater than 60 per cent and the protein content less than 20 per cent, fats and salts being adequate (II to VII)

(*b*) Those in which the protein content is constant at 20 per cent and the white flour content is between 40 and 60 per cent, fats and salts being adequate, and the balance of carbohydrate being made up of purified starch (VIII to X)

(*c*) Those in which the protein content is constant at 20 per cent, fats and salts being adequate, while the white flour content is reduced to below 30 per cent and the balance of carbohydrate made up of purified starch (XI to XV)

The control diets (I and XVI) are not included in these three classes

---

* Abstract of a paper appearing in the July issue of the Indian Journal of Medical Research Published by permission of the Director-General, Indian Medical Service

Goitre occurred in the first and third classes to an almost equal extent (38 9 and 33 3 per cent respectively), but not at all in the second class; this does not mean that diets of this class cannot cause goitre, but that they did not cause appreciable enlargement of the gland in this experiment

There were eight diets (I, II, III, IV, XII, XIII, XIV, and XV) which failed to ensure even a moderate rate of growth These may be excluded as unlikely to be of a composition comparable to any diets used by white-flour-eating peoples They have however, served a useful purpose in the experiment by indicating that insufficiency of vitamins of the B class is a principal dietetic fault concerned in the production of this type of goitre. There are left seven diets (V, VI, VII, VIII, IX, X, and XI) into which white flour entered largely, these ensured a rate of growth which, though not perfect, was at least considerable The following facts in regard to their association with goitre are to be noted.—

1 Those containing 72 per cent or more of American white flour and 15 per cent or less of protein, the fats and salts sufficing for normal needs, caused noticeable goitres in 33 3 per cent of young rats, despite the adequate ingestion of iodine

2 Those containing 20 per cent of protein and between 40 and 60 per cent of American white flour, the fats and salts sufficing for normal needs, did not cause goitre.

3 One diet containing 20 per cent of protein and 30 per cent of American white flour—the balance of carbohydrate being made up of purified starch and the fats and salts sufficing for normal needs—caused goitre in one out of six animals fed upon it, despite the adequate ingestion of iodine

The conclusion is thus reached that diets having the composition of those in Groups 1 and 3 above will cause goitre in approximately 25 per cent of individuals consuming them, despite the adequate ingestion of iodine The amounts of potassium iodide ingested with these diets ranged between 0 4 and 2 6 mg. per rat daily

Among the 16 experimental diets there were two (Nos I and II) which caused goitre in 3 out of 12 animals; no iodine was added to them The goitre arising in consequence of their consumption did not appear to differ histologically from those caused by the other diets The further conclusion is therefore reached that the pathogenesis of this type of goitre was independent of the amount of iodine ingested with the food

Sex-incidence of the Goitre

Of the 96 animals used in this experiment 42 were males and 54 females There were 9 cases of goitre in males, 16 in females, a case-incidence of 21 4 per cent in males and 29 6 per cent in females Taking into account only the goitre-producing diets (V, VI, VII, and XI) which ensured fair growth in the young rats consuming them, there are 24 animals to be considered Of these 13 were males and 11 were females Goitre occurred in 1 male only, while 6 females were affected by it, a case-incidence of 7 7 per cent in males and 54 5 per cent in females Although the figures are small, yet this difference in sex-incidence appears to be sufficiently marked to justify the conclusion that females are much more likely to suffer from this type of goitre than males—a significant conclusion in view of the probable relationship of this type of thyroid change to Graves's disease and myxœdema (vide infra), and of the higher incidence of these conditions in the female sex [9]

Pathology of the Goitre

Macroscopically the goitres are of glistening, fleshy appearance, bright or darkish red in colour, they stand out prominently against the surrounding tissues They are of small size, being from 50 to 100 per cent larger than the normal organ The isthmus is usually prominent, thickened, and broadened. Commonly one lobe is more enlarged than the other, occasionally the enlargement is unilateral

Microscopically the earliest evidence of change is seen in glands which are not appreciably enlarged, but which appear bright coloured at post-mortem examination More or less circumscribed areas (Fig 1)—commonly in the isthmus, the posterior border, and the lower pole of one or other lobe—are seen to be depleted of colloid material or to be in process of depletion The affected area assumes a cellular structure composed of a more or less solid mass of epithelium This mass—the so-called intervesicular parenchyma—increases in bulk at the expense of the colloid containing follicles appearing gradually to invade them and to crowd them out, some of these follicles contain larger or smaller numbers of free cells Here and there the solid mass of epithelium is vesiculated by the collection among the cells of pools of new secretion (not colloid) [9] The cells subtending these pools present the typical features of secretory activity (Figs 1 and 2), rather deeply-staining nuclei located at their base, and faintly basophil and granular cytoplasm Passing from such non-goitrous glands to specimens of the actual goitres, one sees the more extensive crowding out of colloid-containing follicles until in some sections there may be but two or three and occasionally none at all (Figs 3 and 4) Such colloid-containing follicles as exist are of normal appearance, the colloid deeply eosinophil, the acinar cells flattened or more commonly cuboidal, nuclei centrally placed and evenly distributed, and cytoplasm homogeneous and faintly acidophil The whole or almost the whole organ is thus gradually depleted of its stored colloid material and the normal structure of the gland is replaced by tissue in a state of intense secretory activity (Fig 2) Nowhere in the gland is "vesicular budding"—so conspicuous a feature in the experimentally-produced hyperplastic goitre—to be seen The perifollicular reticulo-endothelial system, described by Williamson and Pearse,[10] stands out prominently owing to its affinity for hæmatoxylin; many of its cells are swollen, but the stains used did not permit of the definition of its cytoplasmic granules (Fig 3) Here and there this system is subtended by a number of round cells—sometimes forming considerable collections (Fig 3)—which appear to be lymphocytes In goitrous animals dying between the fortieth and the seventy-fifth day of the experiment these may be the only appearances seen, there being no appreciable increase in the fibrous stroma of the gland and the secretory epithelium showing no marked signs of exhaustion But in goitrous animals which survived to the end of experiment (165 days), and were then killed, this earlier and progressive stage is seen to have given place, in greater or lesser degree, to appearances indicative of a breaking down of the gland's compensatory mechanism In this retrogressive stage exhaustion of more or less epithelia occurs and there is a relative increase in the fibrous stroma of the gland (Fig 4) The process is one of intense *secretory activity* with a gradual depletion of the gland's store of thyroxin-containing colloid and with little or no attempt at completion of its cycle of activity and the replacement of colloid It is a condition which in its *early stages* might possibly be precipitated into one of Graves's disease by such additional excitants as fright, mental worry pregnancy, lactation, and attacks of acute infectious diseases, such as influenza and acute rheumatism In its *later stages*, however, exhaustion of a greater or lesser number of the gland's secretory elements takes place and these are replaced by non-secretory elements in amounts foreign to the normal organ Proportionate degrees of thyroid insufficiency will thus result with clinical manifestations of myxœdema commensurate with the degree of insufficiency

Dr Williamson and Dr. Pearse, to whom sections of *early* cases of this type of goitre were sent for opinion, consider the histopathological picture to be one of intense secretory hypertrophy almost approaching the complete heterotrophy of the *adenoid goitre* of primary Graves's disease,[11] a condition which, if prolonged will result in failure of the gland's compensatory mechanism and the production of a state resembling that to which they have applied the term *lymphadenoid goitre.*[11] That this sequence of events does actually take place is apparent from the series of photomicrographs (Figs 1 to 4) illustrating the histopathological picture from its earliest to its latest stages

Cause of the Goitre

The fundamental cause of this type of goitre is a dietetic one, its exciting cause is a different matter The influence of faulty food in causing it is made apparent by the complete freedom from it enjoyed by well-fed stock rats in this laboratory. The stock diet consists of whole wheat flour (*chapattis*), sprouted grain, milk, butter, and abundance of green leafy vegetables and raw tubers (potatoes and carrots), with fresh meat occasionally The dietetic cause of the goitre lies, therefore, in the differences in quality between the stock diet and the experimental diets In comparison with the former the latter contained an insufficiency of accessory food factors belonging to the vitamin B class,† they were also deficient in vitamin C, in vitamin A, in manganese, and in vegetable juices and roughage (cellulose and the indigestible parts of plants), while they were rich in vitamin-poor carbohydrate *Although it seems* probable from the results of the experiment (Table I) that the insufficient provision of vitamins of the B class was the principal dietetic cause of this type of goitre, yet I am reluctant to attribute it wholly to this cause For the present it is enough to say that it is prone to rise when green vegetable foods and fruit are excluded from a diet containing more than 60 per cent of white flour, less than 20 per cent. of protein, and fats and salts (including iodine) in adequate amounts

There is another aspect of the causation of this type of goitre. All animals in each group were fed alike There would seem at first sight to be no more reason, on dietetic grounds alone, why one or two animals in any one group should become goitrous than that the remainder should not It is true that among the non-goitrous remainder there were some whose thyroids presented changes in *part of the gland* similar to those found in the goitrous organs; but there were others whose thyroids were to all appearances normal Nothing, however, is more striking in the pathogenesis of deficiency diseases[4] than the variability of the effects of faulty food on different individuals and on different organs and tissues of the body In one the nerves, in another the heart, in a third the gastro-intestinal tract may be so injured as to dominate the clinical scene So it may be in the present instance, the faulty diets used in these experiments may have induced in some thyroids a graver state of physiological inefficiency than in others, and the changes in the goitrous glands may represent the attempt made by the physiological subnormal gland to attain to a state of compensation In this attempt it must inevitably fail since its malnutrition renders it inefficient as a machine

On the other hand, the faulty diet per se may not have been the essential cause of the disease, but have favoured the action on an ill-nourished and physiologically subnormal gland of some goitrigenous agent peculiar to the animals which developed goitre The diets with which the goitres were associated gave rise to a physiologically subnormal, and sometimes to a pathological, state of the gastro-intestinal tract, and it is possible that the exciting cause of the disease may have been of intestinal origin and of toxæmic nature I have previously[9] postulated the existence of such "toxæmic goitres" in constipated and imperfectly nourished girls The present paper suggests at once the cause of the intestinal stasis (insufficiency of vitamin B)[4] and of the "toxæmic goitre" which may accompany it *While the cure of* simple goitre which may so rapidly follow the removal of the stasis,[9] without change in the state of nutrition of the subject, lends support to the view that the thyroid enlargement is in such cases of toxæmic origin It may be, again, that faulty diets such as those used in these experiments give rise to different biochemical disturbances in different individuals with the production in some of abnormal metabolites which excite the thyroid unduly or deplete it of the hormone necessary for their combustion

There are thus three sites at which the essential cause of this type of goitre is to be sought The first, in the gland itself, where inefficiency of the thyroid machine may be brought about by its malnutrition with impediment to the normal revolution of its cycle of activity, the second, in the body fluids and tissues where imperfect metabolism may be assumed to result in the production of abnormal metabolites and to cause depletion of the thyroid hormone necessary for their combustion; and the third, in a physiologically subnormal or pathological alimentary tract whence bacterial agents or their toxins may find their way into the circulation and induce pathological changes in the thyroid gland But at all three sites the common factor is imperfect nutrition induced by the faulty food, the general statement I have already made as to the dietetic cause of this type of goitre will serve until we know more of the part played by the thyroid gland in the animal economy and of the biochemical phenomena associated with faulty nutrition

Commentary

In view of the confusion which exists in regard to the causation and prevention of the thyroid diseases included under the generic term "simple goitre" the results of these experiments are illuminating If, as seems likely, the type of goitre here described be found to occur sporadically amongst white-flour-eating peoples, then the view that all "simple goitres" are due to iodine deficiency and preventable by the prophylactic use of iodine must be abandoned The relation of iodine to each type of "simple goitre" must be definitely defined, this has been attempted for the classical type of endemic goitre—the chronic hypertrophic or parenchymatous type; it remains to be done for the diffuse colloid type of endemic goitre

The experimental evidence here provided makes it probable that in Western countries this new type of goitre will be encountered in its progressive stage in childhood and in young women of the working classes whose food contains much vitamin-poor carbohydrate, little suitable protein, and less green vegetables and fruit, and in its retrogressive stage in older subjects whose food has similar faults If this should prove to be so iodine will neither prevent nor cure the disease, but a well-balanced diet rich in vitamins will. These matters can, however, only be decided by clinical and epidemiological observation, and by "goitre surveys" which take into consideration the food habits of the people and are not limited to one section of the community—the children Outside the laboratory it will probably be found that the purity in type of this variety of goitre may commonly be obscured by the interaction, with the nutritional factors which give rise to it, of other goitrigenous influences, such as the ingestion of an excess of lime or of fats, and insanitary conditions of life both intrinsic and extrinsic to the individual Such influences as these may be expected to distort its characteristic histopathological picture and give variety to the characters of the goitres met with in different individuals or in different localities Further, it can hardly be doubted that the pathological features of the "endemic goitres" will be influenced by the food habits of residents in endemic zones, where white flour is the staple article of diet and milk and green vegetable foods are scarce endemic influences may be expected to give rise to a pathological picture in the thyroid gland which will differ in detail from that resulting in localities where whole wheat flour is used and milk and vegetable foods are abundant

---

† Experiments now in progress appear to indicate that there are two fractions in vitamin B a growth promoting fraction and an antineuritic fraction, white flour is not devoid of the latter, but is very deficient in the former, polished rice is very deficient in the latter

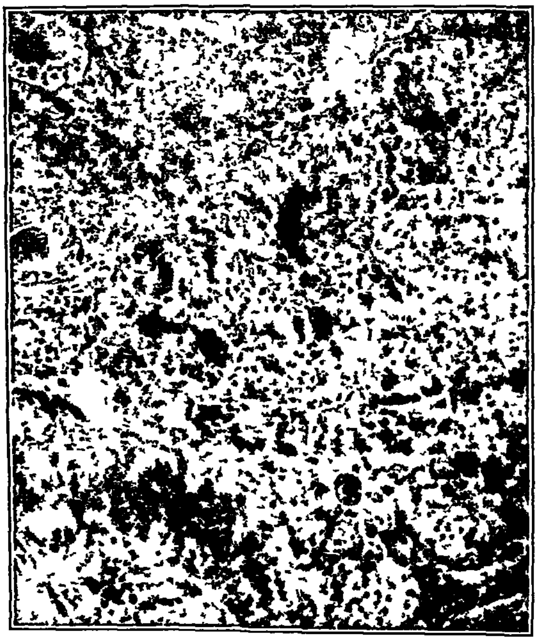
FIG 4.



A late stage of the process showing exhaustion of epithelium and invasion of the gland by non secretory elements, animal died on the 127th day of the experiment

Summary

(1) A new type of goitre has been produced, under experimental conditions in young rats, which is unrelated in its origin to iodine deficiency

(2) It is to be distinguished ætiologically, pathologically, and epidemiologically from the chronic hypertrophic or adenoparenchymatous type of endemic goitre and from the diffuse colloid type of endemic goitre.

(3) The basal factor in its causation is a diet containing more than 60 per cent. of white flour or of vitamin-poor carbohydrate, 20 per cent or less of protein with fats and inorganic salts (including iodine) in adequate amounts, but no green vegetables nor fruit

(4) The goitre arising in these circumstances is characterised by intense secretory hypertrophy which ultimately leads to exhaustion of more or less of the epithelia and its replacement by non-secretory elements and fibrous tissue These changes may be present without any marked increase in size of the gland.

(5) It seems likely that this type of goitre will be found to occur sporadically amongst white-flour-eating peoples, that the subjects of its progressive stage will be prone to develop Graves's disease, following such influences as fright, mental worry, pregnancy, lactation, and attacks of acute infectious disease; and that the subjects of its retrogressive stage will exhibit greater or lesser degrees of myxœdema.

(6) If this type of goitre be found to prevail sporadically in white-flour-eating peoples the additional provision of iodine in the food will not prevent it, but a well-balanced, vitamin-rich diet will

Royal West Sussex Hospital —This hospital has exceeded its income by £2640 this year At the annual governors' court on April 12th sanction was given to sell out investments, or to transfer from the trustees' account sufficient money to liquidate the deficit Not so very long ago the hospital increased its accommodation from 60 beds to 100 beds; it is considered that the change has been thoroughly justified by the use made of the beds From 978 in-patients and 717 operations in 1923 the figures in 1926 were 1280 and 1153 respectively The financial position, however, caused great anxiety A contributory scheme was launched six months ago, and since the annual meeting of the governors a total of nearly 9000 contributions has been received, covering some 20,000 people Compared with the progress of similar schemes in other parts of the country the governors consider that a very satisfactory start has been made, and by the end of the first 12 months it is hoped that the number of contributions will be up to 15,000 Good progress is being made in regard to the centenary scheme which was launched early in the year, the scheme is to raise a sufficient sum to provide additional accommodation, including better quarters for the nursing staff and the establishment of beds for maternity cases

By MEURICE SINCLAIR, C M G, M B, Ch B Edin,
LATE MAJOR, R A M C, SURGICAL SPECIALIST TO MINISTRY OF PENSIONS, SPECIALIST IN FRACTURES AND ORTHOPÆDIC SURGERY, ST JAMES'S HOSPITAL, BALHAM, S W

The subject of fractures has now absorbed my attention for some years past It deals with a somewhat neglected branch of surgery, and I offer during this discourse some practical suggestions which I hope may interest you and at the same time attempt to bring nearer perfection the condition of a patient who may be suffering with a broken bone In bygone days fractures, amputations, lithotomy, and herniotomy were foremost in our surgical procedures Then, with Lord Lister's discovery of the bacterial origin of inflammation and the approach of aseptic technique, a new age began in surgery. Amputations were displaced from their former exalted position and new tracts of the body were conquered in the regions of the abdomen, the thorax, and the brain

The rapid advances made during the last 40 years have cast an illusion over the eyes of the younger generation of surgeons who have, perhaps, thought that all might be cured by the knife alone There has been so much discovered that was new, both to teacher and student, that the treatment of fractures was, for a generation or so, apparently allowed to fall into the background as a subject on which our grandfathers had said the last word

In most of our medical schools the treatment of fractures is only too often assigned to junior officers Nor is this all The demand for beds is so pressing that a house surgeon will gain no favour if fractures are admitted in numbers or retained for long Hence the immediate application of plaster and its attendant evils—stiff limbs, wasted muscles, and pressure sores In each medical school customary methods have during the years become stereotyped, until at the present time it is often possible to name the school in which a man has been trained by the splints and methods he employs for the treatment of any particular type of fracture

Modern Diagrams and Treatment of Fractures

The very commencement of the twentieth century however, marked an epoch in the history of fractures, for Prof Roentgen's discovery of X ray in 1895 and its application to the study we are now discussing wrought a wonderful change in our views and in our methods of treatment X rays enable the surgeon to see the actual condition of the fractured bone, and the radiograph is to the surgeon what the ophthalmoscope is to the ophthalmologist and the cystoscope to the urologist By its correct application he gains information as to the true state of affairs in the condition with which he is dealing, analogous, in diagnostic value, to the exploratory laparotomy of the abdominal surgeon Still more recently the experiences of the great war subjected the accepted modes of treatment and appliances to a supremely severe test, exposed their weaknesses, and forced us to evolve new methods as well as to improve the old

Without good X ray films it is impossible to be sure of obtaining the best results, because a great variety of pathological details may be learnt from a careful study of them

1 The presence of a fracture
2 The variety and position of the fragments
3 A coexisting dislocation of, or other injury to, a joint
4 The presence and situation of gas-gangrene and of air in the soft parts

---

* An address delivered at St James's Hospital on Jan 26th, 1927

5 The presence of bipp

6 The formation and character of callus and the solidity or otherwise of new bone formed

7 Comparisons of films taken if possible in two planes at specified regular intervals during the treatment offers the best means of arriving at a correct prognosis

8 Before operation it can be decided what variety of internal mechanical fixation will be most successfully used for that particular problem

9 While manipulating under the screen immediately before the application of a splint or plaster-of-Paris one finds out by verification the areas on the limb to which the reconstructive forces have to be applied in order to maintain the corrected position of the fragments

In this country, as you are aware, the British Medical Association appointed a Special Committee of Inquiry in 1912 The records have been compiled with such care, accuracy, and impartiality, that it is a document of the first magnitude Taking all the statistics together, they prove that if the anatomical result is good the functional result is good in 90 per cent of cases, while if the anatomical result is bad or moderate a good functional result is obtained in only 29 *per cent* of cases My own experience entirely supports these findings

Each new fracture is a *fresh problem* and its diagnosis and treatment cannot be controlled by a set of rules which were formulated and did excellent service at a time when the surgeon's vision had to be projected through his finger-tips X rays must be used at every stage if one is to be successful in the treatment of fractures, it is also essential that a mobile X ray plant should be available, to be brought to photograph the patient's limb when he is lying in bed The moving of a patient to an X ray room is liable to interfere with the extension which is being maintained, and thereby may jeopardise the end-result of his treatment If mobile X ray plants were available for the use of any practitioner who required one, in my opinion great advantage would accrue both to the patient and the profession This is no new suggestion, and it was actually in practice at No 8 Stationary Hospital, which was a hutted unit, from January, 1916, until the end of the war. On account of the principles adopted for treatment and of my strong objection to moving patients on a stretcher to the X ray department, it became necessary for us to devise a mobile X ray plant, which was placed on a B R C S motor ambulance, and the scheme turned out to be so satisfactory that radiographs could be eventually taken anywhere in Boulogne base by one of these specially fitted motor-cars

In institutions I am convinced that segregation of fractures under the care of surgeons and nurses who have a special aptitude for and training in the subject will turn out the best results and be the quickest means of returning most if not all, of the lost functions

It is to Sir Almroth Wright I must tender my unforgettable thanks for pleading with and obtaining permission from G H Q in France to first segregate the fracture cases and for assembling the selected personnel and matériel at No 8 Stationary *Hospital*, Wimereux, in 1915 The results, I was informed, were so satisfactory that Sir Robert Jones and Sir Arbuthnot Lane started the hue and cry, and other similar organised units were commenced both in Great Britain and France, and such beneficial results followed that I had hoped that the scheme which had been proved such a success would be more generally adopted than it has been in civil and military hospitals after the war

Importance of First-aid Treatment.

Even after the countless lessons we learnt in the war, is it not tragic to still hear Sir Robert Jones state that "the treatment of fractures in this country leaves much to be desired"[2] *When a medical man* is called upon to attend a case of fracture of a limb, the occasion is generally that of an accident *on* a race course, a motor smash on a country high road, or, possibly, an ordinary street or factory casualty In the latter two instances one is more conveniently placed, as the personnel and material for treatment are probably more ready to hand, whereas in the former urgencies this is generally not so But in all cases the treatment should commence from the time that the injured person is first seen by the surgeon or first-aid worker, and should be continuous and consecutive until cure is effected

Even the help of modern fracture equipment, the X ray screen and a large and varied experience of manipulative treatment of deformities does not necessarily ensure that this form of treatment will be unfailingly successful in producing perfect reposition; it is therefore inevitable in a percentage of cases to have to apply such useful expedients as mechanical pulls, and when these fail then to attack the seat of fracture by direct operation with plating, wiring, bolting, bone grafting, &c When this is indicated the operation should be done within a short space of time after the injury, and then *only* when perfect asepsis can be obtained In any case, the surgeon's immediate action is demanded by the fracture which may be either simple or compound

The same general initial treatment by immobilisation, as laid down by Hilton in his classic on "Rest and Pain," in 1863, is as essential for broken bones and their surrounding soft parts as for every other kind of damaged tissue In a fracture case the only condition which has a prior claim to immobilisation in receiving attention is hæmorrhage

During first-aid treatment, if there is serious bleeding, the wound must have first attention, but when the patient is in no danger from the loss of blood the limb should at once be immobilised by extension and the clothing afterwards cut away for the purpose of applying a temporary dressing to the wound The further progress of the case depends upon the promptness and thoroughness with which the management of the wound is carried out, but I certainly do not advocate the mass excision sometimes seen during the war Excision of tissues should always be as conservative as possible

The principles of the treatment of hæmorrhage are well established but may I strike a note of warning for the cautious use of the tourniquet and to restrict its use to cases of dire necessity The employment of it, except as a temporary measure during an operation, is often a source of danger both to life and limb However if it has been applied it should be made open to the knowledge of all, and it is the duty of the surgeon who next sees the patient to remove it at once and to examine the limb so as to ascertain whether the bleeding has ceased, if not, to employ proper measures for its arrest

In all cases in which it can be efficiently carried out steady digital compression is the best method to employ, but I have occasionally placed an elastic tourniquet loosely round a splinted limb and sent an attendant with instructions to draw the ends gradually tight if necessary, but only up to that point which stops bleeding There is often under the strain of an emergency an inclination to apply it more tautly than is required to prevent the escape of blood and this may eventually determine the fate of the limb or even that of the life

Essentials of Treatment

The first essential is to steady the limb and temporarily fix the broken bone or bones, so that no further movement of them is permitted · by so doing hæmorrhage further laceration of soft structures and shock, which is markedly aggravated by pain, by loss of body heat, and by hæmorrhage will be minimised if not prevented Thus a patient with a fractured femur may if he be kept quiet, properly splinted, and adequately warmed never exhibit any signs of shock, while another with a similar injury may pass into a dangerous state of collapse if insufficiently splinted and exposed to cold Shock is after all proportionate to the sum of the intensities of the factors causing it The initial force used for the purpose of extending the limb, when once it has been applied, should never be allowed to relax as by so doing the fragments are made to travel. These may be jagged sharp, and dangerously spiked ends, especially in oblique and spiral fractures, and in comminuted cases the fragmentary bone may be in extraordinary penetrating shapes and positioned in every direction varying according to the tension exerted on the tissues in which they are embedded, and every time they are allowed to return in the recoil they may, perchance, retrace their path, but how often are new tracks made both in the early stages of treatment and later during manipulation with the possibility of damaging important vessels and nerves, and not only this, but each thrust into the old or into a newly manufactured passage will aggravate the exudation in simple fracture, and spread infection as well much more widely in the compound one Muscular and areolar tissue have comparatively a very small resisting power to infections, and this is still further lowered by these additional traumata

For these reasons the extending force should be continuous and never relaxed from the first pull until we see early callus around and between the cleavage sufficiently firm to cement the fragments together when the consideration of the early movements of the joint will, in their turn, come before us and be carried on through that period when the callus can be bent and angulations have, therefore, to be carefully guarded against up to the time that the union is solid and the limb need no longer be held under restraint

The Value and Range of Usefulness of the Thomas Splint

In the case of the upper extremity, bandaging the arm to the side may perhaps, be sufficient as a first-aid measure, but in the case of the lower extremity some form of splint is required, and there are two splints which do efficiently meet the case in all fractures of both upper and lower limbs These two splints have been so well tested and proved in the Great War, that I cannot conceive any more critical trials to which an apparatus could be subjected

In the leg, the *first-aid treatment of all fractures above the ankle-joint* can be efficiently carried out by the application of the Thomas knee splint, which is by far the finest piece of apparatus in our fracture equipment It is applied in the following way —

If there be a selection of splints with different sized rings to hand, then the transverse circumferential measurement of the thigh over the trousers should be made at the gluteal fold To this figure add 1 inch to allow for the obliquity of the ring and 2 inches for possible subsequent swelling and this should be the inside circumferential measurement of the padded ring Thereby all accessory padding which would be *necessary for an unduly large ring* will be obviated

Maintaining manual extension on the ankle *all* the time, the leg is threaded through the ring of the splint without removing the trousers The ring is pushed up gradually and firmly against the tuber ischii and kept there by the operator, who holds the distal end of the splint against his own thigh, at the same time supporting the patient's leg posteriorly at the site of fracture with one hand and maintaining the extension on the ankle with the other, which is held underneath the inner side bar An assistant takes a 6-inch roller bandage, ties the end to the outer side bar near the ring, and passes it behind the thigh from side to side, first over the inner bar and then back over the outer one, and so on until the whole of the posterior aspect of the limb is supported, the bandage is then fixed to one or other of the side bars, an assistant now takes the extension on the limb from the operator

If the operator has a " boot clamp " he fixes it obliquely to the sole of the boot, if not, he then takes a rigid metal rod or skewer about 12 inches long and 3/16 inch in diameter, pointed at one end This is passed obliquely through the boot between the sole of the foot and the sole of the boot The hole on the outer side should be about 3 inches from the anterior surface of the heel and the inner hole 1 inch from this same surface This allows the leg to lie and to be fixed in external rotation, which is the natural attitude of the leg in the recumbent position, and the one in which it ought always to be ultimately splinted A cork or narrow roller bandage is placed over the pointed end of the skewer for safety and a piece of tape or bandage attached to each extremity of the skewer These are passed, the one just above the level of the side bar and the other just below it, made taut and tied to the V shaped notch at the end of the splint, with sufficient tension to maintain the requisite extension If a boot clamp or skewer be not available the extension can be made with a timber hitch of bandage

The patient is lifted on to a stretcher and a "suspension bar" is applied, from which the side bars of the splint are slung After a limb has once been splinted, the side bars of the Thomas should never be allowed to rest on the same plane as that on which the patient's body and sound leg are lying

If this occurs, the side bars fall back and the limb is forced too far forward, thus increasing the deformity, causing pain, and so altering the correct relative position of the limb to the splint into a faulty one An alternative method of raising the splint is either to attach a "splint prop" to the end of the splint, or to rest the end of the Thomas below the level of the heel of the boot, on some form of support, such as rolled-up clothing, &c , but a suspension bar, if available, is far more efficient

The clothing should be cut off the leg at the site of the *fracture, so as to deal with the wound in a compound* case, and in a simple one to be warned if the bone ends are likely to come through the skin

If a wound be present, the skin round it should be sterilised by painting with 3 per cent picric acid in methylated spirit, any obvious dirt or other foreign body picked out, and the picric solution applied to the superficial surface only of the wound, which is then covered with a sterile dressing, and a prophylactic dose of tetanus antitoxin given A firm pad may be placed on either side of the knee between the limb and the side bars and the leg and the splint bandaged at this level, this will give greater security, and will compensate for the extension through the foot not being a very great one

Cotton-wool or padding should be placed in the space, if any, between the thigh and ring of the splint, so as to make an unduly large ring fit more accurately Any such padding between the outer bar and the thigh wall will prevent the ring from slipping inwards, losing its purchase against the tuber ischii *and so coming* in contact with the middle line of the perineum and the symphisis of the pubes But none of these expedients can be assumed as lasting, nor can they be compared in any degree to the efficiency of a correctly fitting ring

Padding between the anterior half of the ring and the anterior surface of the thigh will render it impossible for the leg to be lifted up into the forepart of the splint thereby allowing the ring to slip up beyond the ischial tuberosity This is an all-important point, for the tuberosity is the only place on which the counter-extension can be taken

Too much extension must not be taken through the foot, and this extension must only be considered as temporarily applied for transport to hospital or nursing home, where permanent extension is substituted as soon as possible If the temporary extension is too great or persisted in too long, pressure of the boot, especially in cold weather, will cause obstruction of the dorsalis pedis artery This remark similarly applies to extension by means of *any noose round the ankle or wrist*

First-aid treatment of the arm —Every fracture above the lower third of the forearm can be efficiently treated by the application of the "swivel arm Thomas splint" This instrument differs from "Thomas knee splint" only in that the ring is round instead of oval and made to swivel at the points of attachments to the side bars, to which it does not lie obliquely *The application* of the splint is very simple

A temporary extension is taken by means of a "timber hitch" of bandage placed over the well-padded wrist The two ends of the bandage are tied to the end of the splint, with a pull sufficient to immobilise the fracture The counter-extension is taken from the anterior and posterior axillary folds when the arm is at the side, but from the side wall of the chest in the region of the armpit when the arm is abducted This apparatus allows the arm to be brought into the side of the body without increasing the extension and so facilitates the transport of the case

A circular bandage is applied enclosing the arm and side bars from the hand up to the ring of the splint in order to complete the immobilisation of the fracture The splint is equally suitable both in the initial and subsequent treatment of any fracture of the arm from the shoulder downwards, but for permanent treatment additions are superimposed to the splint and the patient remains recumbent. The fracture having been extended and immobilised the patient is now ready for transport in an ambulance or train He should be kept warm to combat shock and pain until he arrives at hospital, and morphine may be administered with the same objects in view On admission to hospital the patient is not necessarily removed from the stretcher at once A varying degree of shock may contraindicate removal and suggest rather rest and resuscitative measures for some hours Deaths from shock were eventually reduced from 80 per cent in 1915–16 to 20 per cent in 1917–18 by the early efficient application of the Thomas splint

As soon as the patient is in a fit state, anteroposterior and lateral radiographs should be taken or a stereoscopic pair may be substituted, if the injury is too high up for the lateral view to be secured The further procedure will be governed by the clinical findings and the interpretation of these radiographs

The possibility of a nerve lesion should always be considered Injuries of the peripheral nerves are liable to be overlooked, as the symptoms are frequently overshadowed by the manifest pain at the site of the fracture It is preferable to make this diagnosis before a general anæsthetic is administered. Furthermore, a more accurate prognosis can be offered

If perchance X ray examination is not available, then the fracture is put up in the best position as ascertainable by the eye and hand, and by comparing the measurements with the other limb Extension is applied until reduction of deformity is judged to have taken place and a second pair of radiographs, if possible, is taken with the patient in bed without altering any details of splinting This will afford a correct appreciation of the condition which is present, and prove conclusively if the reduction or setting of the fragments has really been accomplished, or if further manipulation be required

When the position is satisfactory the next pair of radiographs is taken when the fracture is beginning to organise, and this gives an insight to the progress of the case and if the correction is still being maintained

When callus is visible further attempts to obtain exact apposition (not already obtained) will no longer be possible unless open operation is undertaken The necessity for this will, of course, depend on the amount of deformity presented, the loss of function that will follow if the displacement is not dealt with, and the delayed convalescence which will ensue

However young callus can be bent, and may be likened to a candle in a candlestick on a hot day in summer It will bend to almost any degree, and so will callus if it be subjected to a gradual and constant force But, just like a candle, it will crack if too abrupt a strain be put upon it, such as a speedy attempt to correct deformity Still the correction of alignment can often be obtained by a slow and regular stress Before allowing a patient to walk without the aid of apparatus, two radiographs should always be taken in planes at right angles to one another This is the most accurate way of estimating the amount of consolidation that is present in length, in breadth, and in thickness It is sometimes possible in a recent fracture to obtain a radiograph in one plane which will not show any bony lesion whatsoever, whereas one taken at right angles to this will reveal gross deformity, in this case a grave error in diagnosis and prognosis will result from the taking of the picture in only one plane

A fracture, from the point of view of treatment, must be considered not only as a solution of continuity of bone, but also as a lesion possibly affecting muscles, vessels, joints, ligaments, nerves, &c The ideal treatment of a fracture should have for its object complete anatomical reposition of the injured tissues with complete restoration of functional power to the effected part Our aim, therefore, in the treatment of every fracture should be to produce a limb in the most expeditious way as nearly as possible the equal of its healthy fellow, both in function and in appearance

It is impossible to conceal the reality that a great deal of restorable function is lost by lack of proper early attention and that subsequently countless cripples are produced whose only real enjoyment of life is to blackguard us as a profession or the institution in which they were treated

I feel sure that improved results will be *only* obtained when some well-tried method which is efficient, really simple and comfortable is more generally taught and employed

THE EXPERIMENTAL PRODUCTION OF IMMUNITY AGAINST METAZOAN PARASITES,

AND AN INVESTIGATION OF ITS NATURE

By D B BLACKLOCK, M D.EDIN, D P.H, D T M,
PROFESSOR OF TROPICAL DISEASES OF AFRICA, UNIVERSITY OF LIVERPOOL, DIRECTOR, SIR ALFRED LEWIS JONES RESEARCH LABORATORY, SIERRA LEONE,

AND

R M GORDON, M D DUB, D P H D T M,
ASSISTANT DIRECTOR, SIR ALFRED LEWIS JONES RESEARCH LABORATORY

THE experiments described briefly in this paper were carried out in Freetown, Sierra Leone, during the year 1926 and part of 1927 The work was undertaken with two main objects The first of these was to confirm statements previously made regarding the existence of immunity to metazoan parasites, the second was, given such confirmation, to discover whether the laws which govern metazoan immunity are similar to those which govern various forms of bacterial immunity The full account of our experiments will shortly be published in the *Annals of Tropical Medicine and Parasitology*

The experiments were conducted according to a plan which has enabled us to afford complete proof of the existence of an acquired immunity which conforms with the following rigid definition —

> An immunity acquired as the result of previous infection or vaccination, and involving the death of the metazoan parasite in the host within a specified time

This definition clearly excludes the condition of metazoan tolerance described by various writers, in which a host naturally susceptible to, and adversely affected by, a given metazoan parasite may harbour increasing numbers of such parasites with no increase of, or even with diminution of, adverse effects. Weinberg and Julien [1] (1911) concluded as a result of their experiments that horses infected with a certain number of ascarids gradually immunised themselves against the action of the products of secretion of these parasites Gordon's [2] (1925) record of the heavy parasitic infection with ankylostomes which occurred in natives in West Africa, in whom little adverse effect of the infection could be observed, probably comes under this head. Such conditions are not immunity in the sense in which we use the word above, for although there appears to be an immunity acquired against the toxic effects produced by the parasites, the parasites themselves are not destroyed

Previous Records

Surprisingly few records are in existence of the experimental proof of immunity acquired against metazoan parasites as a result of previous infection Fujinami [3] (1916), in a paper entitled Immunity to Macroparasitic Disease, Can it be Acquired ? records such acquired immunity against schistosomes A horse which had recovered from an attack of schistosomiasis and was free from infection was exposed with two control horses to water heavily parasitised with cercariæ One of the controls died within two months, and at the autopsy over 20,000 worms were recovered from its portal system, the second control was killed after an interval and from its portal system 10,000 worms were recovered In the experimental animal which was killed at the same time as the second control, not a single worm could be found in spite of the most careful search Blacklock and Thompson [4] (*1923*) proved experimentally that immunity can be acquired both by man and animals against the larva of a fly which causes cutaneous myiasis in Africa The fly is *Cordylobia anthropophaga*, popularly known as the tumbu fly, its larva penetrates the skin of man or animals and resides there during the period of larval development which lasts about ten days, it produces lesions resembling boils, the immunity is produced by previous attacks and it was shown not to depend on age

That immunity against certain metazoan parasites may in some cases develop as the result of age alone, quite apart from previous infection, appears proved by the work of Herrick[5] (1925) who experimented with chickens as the host animal and the worm *Ascaridia perspicillum* as the metazoan parasite This observer found that chickens of over 100 days old have, by their age alone, no previous infection having occurred, developed a high degree of immunity against the parasite Previously, Ransom[6] (1921) had found that young chickens were easily infected with the gapeworm, *Syngamus trachealis*, while old chickens were difficult to infect, again (1922) the same writer had concluded that age itself was an important factor in the production of the complete or partial immunity enjoyed by pigs of mature age against ascaris

The Present Experiments

For our experiments we again made use of the larvæ of cordylobia, largely because they can be kept under observation during the entire period of their parasitic life, which is spent in the skin and subcutaneous tissues. The details of the technique of breeding, maintenance of larvæ, application to and observation in the skin, are too long for inclusion here and will be found in the fuller accounts referred to above

Fifty-eight guinea-pigs, some imported and some local, were used for the series of experiments, and in all 1650 first instar larvæ were placed on the skin, observed to penetrate it, and thereafter kept under daily observation for a period of six consecutive days Those larvæ which survived to the sixth day were classed as developing normally, this has the disadvantage of telling against our results, because some larvæ in semi-immune animals were able to survive till the sixth day, but proved unable to complete their parasitic life and died in the host animal, it has, however, the advantage that all larvæ could be accounted for, which we found would have been quite impossible in experiments on this scale if we had adopted the obvious method of collecting the larvæ as they emerged from their host prior to pupation

The Production of Immunity—Regarding our figures as a whole, the fact which primarily impresses us is that the first experimental infection with larvæ yields many more larvæ attaining to the sixth day of development than all the subsequent applications taken together Thus of 472 larvæ placed upon the guinea-pigs at their first experimental infection—that is to say, at their first test—231 (49 per cent) survived to the sixth day, whereas of 1178 larvæ put on at all the subsequent applications combined, only 78 (7 per cent) survived to the sixth day We found at the same time that the local guinea-pigs differed from imported English guinea-pigs in their resistance to the development of the larvæ, thus of 180 larvæ applied at the first test of local guinea-pigs only 60 (33 per cent) developed, whereas of 292 larvæ applied at the first test of imported guinea-pigs, 171 (59 per cent) developed We see, therefore, that local guinea-pigs possess a relative immunity compared with imported animals and that both local and imported guinea-pigs acquire a great degree of immunity as a result of previous infection

The Nature of the Immunity—At the first we believed we were dealing with a general immunity affecting the whole animal body, this was a natural assumption from the figures we were obtaining, which showed a steady diminution of positive results in successive tests of the same animals, the steadiness of the diminution was due to part as we shall show later, to the method of experimenting

That we were unable to obtain any reactional evidence of the production of general immunity was, however, significant For example, not only was the repeated endeavour to confer passive immunity by the injection of the whole blood of immune into non-immune animals entirely unsuccessful, but so also were all our attempts to demonstrate the presence of antibodies in the serum of immune animals Complement-fixation and precipitin tests were negative, the whole blood and serum of immune animals possessed no larvicidal properties in vitro, whole blood defibrinated, and active and inactivated serum of immune animals were neither lethal to larvæ living in contact with them for several days, nor did their influence prevent the development of such larvæ in a normal manner when subsequently placed on non immune animals Corroborative evidence of the fact that antibodies in the general circulation play no easily recognisable part in this form of immunity was afforded by the results of attempts to immunise animals by the intraperitoneal and subcutaneous injection of third instar larvæ in the form of an emulsion Three animals were inoculated by each route and tested after a suitable interval, in neither series was any degree of immunity acquired—in fact at the test of the three animals which had received intraperitoneal injections more larvæ developed than would normally have developed in untreated animals It was striking therefore, in view of the above results, to see that not a single larva could develop at all out of 50 put on an area of skin on an immune guinea pig while of 50 similarly applied to an identical area of skin on a non-immune guinea-pig 30 developed normally.

Local Immunity—We were led to the conception of the immunity as a local one by the fact that an animal which had proved at repeated tests to be immune on one skin area might yet permit the larvæ to develop at least partially on another area as yet not tested. This fact escaped our notice at first, because for the sake of convenience we were in the habit of using the same skin areas for repeated tests, and when the animal duly became immune in these tested areas, we thought of it as generally immune Having been driven by our results to the idea of a local immunity, we continued our experiments from this point of view, the highly interesting and important conclusion was thereby reached that we were, in fact, dealing with an immunity which is at first localised to the site of larval development In order to bring out this fact it is necessary to compare (1) the results of a series of tests of a number of animals on unselected skin areas with (2) the results of a series of tests of selected skin areas on the same animals. The figures for comparison are set out in the table from which it is seen that a series of tests of skin areas has the effect of producing a completely negative result after the sixth test, whereas a series of tests of animals on unselected areas gives irregular results Thus it is seen that even the twelfth test of animals may give a result as positive as any but the first test In addition to the conclusive evidence which the table affords of the production of local immunity, we have also here evidence that animals tested frequently in any area tend to become generally

Table showing that Repeated Application of Larvæ to the same Skin Area Results in Complete Local Immunity

Consecutive tests of animals			Consecutive tests of skin areas in the same animals		
No of test	No of larvæ put on	Percentage of larvæ which survived to 6th day	No of test	No of larvæ put on	Percentage of larvæ which survived to 6th day
1st	472	49	1st	614	43
2nd	194	12	2nd	215	10
3rd	156	6	3rd	210	4

immune, which is an indication that the immunity spreads

Spread and Persistence of the Immunity—Evidence of the spread and persistence of the immunity was obtained by direct experiment Six animals were chosen which at their first test with 29 larvæ had a percentage of 62 surviving; at an interval of three months, after being rendered immune on certain regions, they were tested on new regions with 48 larvæ of these only 10 per cent developed

The persistence of the immunity was tested on the same animals by applying larvæ to the previously immunised areas At the first test, as we have shown, 62 per cent of the larvæ applied underwent development, at the test at the same areas three months after they had been immunised only 2 per cent developed out of 46 larvæ applied It should be noted that during the intervening period the animals were kept carefully screened so as to avoid casual infection

It seems clear, then, that the immunity established locally by previous infection spreads out from the original site of immunisation, and that it persists for at least three months. in all probability it lasts much longer, but the limits have not yet been determined by us As would be expected, it was found that animals which had been immunised and were then exposed to repeated infection during a period of over seven months showed a more definite spread and a stronger persistence of the immunity

Association of the Immunity with the Tissues—We have enumerated the forms of experiment which were undertaken in order to prove, if possible, the association of the immunity with the general circulation; these experiments proved that there was very little, if any, such association recognisable by the usual tests Now we may mention certain experimental findings which indicate a definite association of the immunity with the tissues It was found that.—

1 Larvæ which penetrate an immune area of an animal are dead in the skin in the majority of cases within a period of 40 hours—i e., at a time when they are still lying very superficially and are not yet in contact with the blood-vessels

2 When a piece of immune skin was grafted on to an animal which was not immune, the grafted skin retained its immunity, and the surrounding skin of the non-immune animal developed immunity, conversely a graft from a normal animal developed immunity after being planted on an immune area.

3 Skin reactions when larvæ penetrate were not observed in normal animals; in immune and semi-immune animals skin reactions, swelling, and redness usually occurred on the areas previously treated, a reaction was observed to occur on the immune skin grafted on a non-immune animal

4 The immunity is reproduced in the new skin which grows on a denuded portion of an immune area

One series of experiments, however, shows that the skin may depend indirectly on the circulating fluids for its immunity The immunity present in living skin did not persist in the same skin when detached from the animal, larvæ living in it at room and incubator temperature for as long as they did in normal skin also detached.

Eosinophilia

Owing to the prominence which is often given to the occurrence of eosinophilia in many infections with metazoan parasites, we attempted to come to some conclusion as regards its significance in immunity to such parasites In each case our percentage of eosinophils was derived from a count of a thousand leucocytes and this part of the investigation involved the differential counting of nearly a hundred thousand leucocytes The conclusions reached were as follows —

(*a*) Metazoan infection is not invariably accompanied by eosinophilia

(*b*) Immunity against a metazoan parasite may develop without the occurrence of eosinophilia, either general or local

(*c*) Intense eosinophilia, either general or local, may exist without any immunity being present.

(*d*) Intraperitoneal injections of emulsions of third instar larvæ reduce the eosinophil percentage

(*e*) Subcutaneous injections of, and applications to, the scarified skin of third instar larvæ as emulsions increase the eosinophil percentage

Nature of the Immunity and its Production by Artificial Means

It has been possible to exclude both mechanical damage to the skin and the condition of athrepsis as the cause of the immunity Attempts to break it down once it is established, by intraperitoneal injections of oil by the administration of certain drugs and by damage to the superficial layers of the skin have failed We are, in fact, dealing with a true immunity against metazoan parasites, and it is a solid immunity The remarkable phenomena brought to light by the work of Besredka on local immunisation in the realm of bacteriology may find a parallel in metazoan immunity

Some preliminary experiments have been made on production of the immunity by artificial means. While intraperitoneal and subcutaneous injections failed to produce it, much greater success attended our efforts when we permitted larvæ to penetrate and then removed them, and again when we applied emulsions of larvæ to the skin. Of 12 animals treated by these means four developed immunity on the area treated, and the remaining eight in the majority of cases gave a much lower positive rate than normal

BLOOD-SUGAR CURVES IN CERTAIN MENTAL DISORDERS.

BY ROY N CRAIG, M D DURH, D.P.M LOND,

PHYSICIAN-IN-CHARGE OF NERVOUS DISEASES TORBAY HOSPITAL, TORQUAY, AND THE DISPENSARY, EXETER.

THE carbohydrate metabolism has been investigated in 90 cases of mental disorder, in the hope that either a typical curve might be found correlating with any particular disorder or that some further light might be thrown on the pathology of the diseases

Technique.

In this work the method of Calvert[1] has been used as being the most satisfactory

A quantity of blood (about 250 mg) is collected from a finger prick into a small platinum capsule and weighed on a torsion balance It is immediately dropped into a tube containing 7 3 c cm of distilled water, and when hæmolysis has occurred 0 3 c cm of 2/3 N sulphuric acid and of 10 per cent sodium tungstate added. After shaking and allowing to stand for a few minutes, the blood proteins are completely precipitated, and the mixture is filtered through a starch-free filter paper. Five c cm of the protein-free filtrate (i e, five-eighths of the original quantity) are pipetted off into a special tube and boiled for six minutes with 2 c cm of alkaline copper tartrate solution Two c cm of phospho-molybdic acid reagent are added the whole made up to standard volume (12 5 c cm) with distilled water, and the tubes shaken and set aside for the colour to develop fully Instead of comparing this colour with that produced under the same conditions with standard glucose solutions, Calvert has introduced a fixed colour standard in glass with which the solution to be tested is compared by means of a colorimeter. He has also worked out a curve of correctives for copper reduction, thereby eliminating an appreciable error with high and low glucose concentrations.

In all the cases examined a meal of 50 g. of glucose in 8 oz. of distilled water was given following a six hours fast, and blood-sugar levels were obtained at half-hourly intervals up to two hours

---

Summary of Cases

Ninety cases of mental disorder have been investigated and belong to the following types —

Anxiety neurosis	50
Epilepsy	15
Melancholia—early agitated, late agitated, involutional, recurrent	25

The cases of anxiety neurosis have been drawn from the Out-Patients' Department for Nervous Diseases at Exeter, the Torbay Hospital, Torquay, or from private practice, and are uncertified Clinically, the majority of these cases had physical signs of tachycardia, palpitation, and a systolic blood pressure of under 115 Mentally, they were over-anxious, hypersensitive, and hypochondriacal, often with some degree of phobia (Table I)

TABLE I —*50 Cases of Anxiety Neurosis*

25	11	18	2	17	135	50	11	19	205	165	155

From this table it will be seen that the starvation level is within normal physiological limits in 35 of the cases, and is above this limit in the remaining 15 All show an appreciable rise of blood-sugar values after half an hour, though there is considerable variation in the resulting hyperglycæmia One hour later only 4 cases show any tendency to fall, and there is an increase in sugar values in every other case, many of these readings are high and markedly above normal One and a half hours later 13 cases are still rising, 4 remain at the level reached half an hour previously, and the rest show the intervention of the storage mechanism. At the end of two hours only 6 cases have regained their fasting level, and many still show high values

TABLE II —*15 Cases of Epilepsy*

Case No	Starvation level	After glucose meal (hours)				Case No	Starvation level	After glucose meal (hours)			
		½	1	1½	2			½	1	1½	2

7	11	15	19	16	12	15	105	15	2	21	19
8	1	17	12	12	1						

Fifteen cases of epilepsy were investigated All were subject to major attacks, and were on luminal treatment at the time of investigation They were drawn from the same source as the cases of anxiety neurosis, and were all uncertified (Table II)

These cases show a wide variation in their curves, only 5 appearing to be justifiably counted as normal in their reaction to the glucose meal After half an hour all but one give evidence of an appreciable rise, which is maintained or increased in all cases except 6 In 8 cases the values are reduced at the end of an hour and a half, but few have reached their starvation level point. Two hours after the meal 7 cases show higher values than at the commencement of the test

Twenty-five cases of melancholia were investigated and have been divided into four groups clinically —

(*a*) Early agitated melancholia, in which the disease had lasted only three or four months and was not apparently associated with the climacteric

(*b*) Late agitated melancholia, in which the symptoms of agitation had lasted over a year, and in some cases up to five years

All the patients belonging to these two groups were under certification (Tables III A and III B)

TABLE III A —*6 Cases of Early Agitated Melancholia* TABLE III B —*5 Cases of Late Agitated Melancholia*

Case No	Starvation level	After glucose meal (hours)				Case No	Starvation level	After glucose meal (hours)			
		½	1	1½	2			½	1	1½	2
1	2	—	11	14	19	1	07	12	18	13	11
2	18	—	12	15	1	2	08	1	12	16	07
3	12	—	1	13	11	3	07	12	17	17	09
4	12	—	09	13	1	4	08	11	15	11	08
5	11	—	09	14	1	5	07	11	15	11	11
6	11	179	18	18	12						

In Table III A all show evidence of defective blood sugar regulation

In Table III B all show a definite degree of hypoglycæmia in the starvation level, but are comparatively normal in their reaction to the glucose meal

(*c*) Involutional melancholia, in which the depression was apparently associated with the climacteric, and was accompanied by bouts of vasodilatation, menorrhagia, or amenorrhœa

(*d*) Recurrent melancholia (manic-depressive psychosis) All except 2 of these cases were certified, and the tests were carried out during an attack of depression (Tables III C and III D)

TABLE III C —*7 Cases of Involutional Melancholia* TABLE III D —*7 Cases of Recurrent Melancholia*

Case No	Starvation level	After glucose meal (hours)				Case No	Starvation level	After glucose meal (hours)			
		½	1	1½	2			½	1	1½	2
1	12	17	15	13	09	1	1	13	16	15	11
2	10	16	19	16	11	2	12	17	22	22	22
3	12	18	18	15	13	3	11	13	16	13	11
4	08	11	15	15	25	4	2	21	22	2	18
5	08	11	15	19	12	5	1	13	16	15	07
6	08	13	19	28	23	6	08	11	13	19	—
7	09	12	16	18	21	7	13	155	21	19	1

In Table III C the starvation levels are within normal physiological limits, but there is a tendency towards sustained high values

In Table III D the starvation levels are within normal limits, and only three cases fail to return to their original value There is a tendency to reach high levels during the course of the meal

Conclusions.

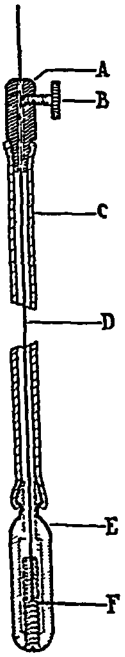
From the above results it will be apparent 1 That there is no characteristic curve for any of the disorders investigated 2 That in anxiety neurosis, however, a failure to return to the original starvation is present in 87 per cent of the cases 3 This failure is in all probability accounted for by a mobilisation of blood-sugar to counteract some toxic process, or by a partial suppression of the pancreatic hormone induced by a similar process 4 It would appear unlikely that the symptoms of mental anxiety are the primary cause of the high levels reached during the meal, as practically none of the cases showed a high starvation level indicating excessive action of the thyroid-adrenalin system prior to the ingestion of the glucose 5 In the cases of epilepsy and melancholia investigated, an apparent defect in carbohydrate metabolism is present 6 The irregular types of curve obtained in certain cases of melancholia are in all probability due to a lack of balance in the endocrine system, as considerable improvement in the mental reaction and type of curve has followed thyroid and adrenalin treatment

I should like to take this opportunity of thanking Dr Porter Phillips for his courtesy in allowing me to carry out part of this work at Bethlem Hospital; and also Captain Mann, of the Maudsley Hospital, for his kindness and help

Clinical and Laboratory Notes.

NOTE ON AN
ADDITION TO THE REHFUSS STOMACH-TUBE.

BY E. M. WATSON, M D WEST. ONT, M R C.P. EDIN,
ASSISTANT PROF OF CLINICAL MEDICINE AND INSTRUCTOR IN PATHOLOGICAL CHEMISTRY IN THE UNIVERSITY OF WESTERN ONTARIO, CANADA



IT is the experience of those who use the fractional method of gastric analysis that many patients have difficulty in swallowing the Rehfuss or Ryle type of stomach-tube Owing to the flexibility of the rubber, little or no assistance can be afforded to the passage little or no assistance can be afforded to the passage of the instrument through the pharynx and down the œsophagus It frequently happens, therefore, especially in patients unaccustomed to the use of a stomach-tube, that it tends to coil up in the mouth or pharynx, giving rise to excessive secretion of saliva and much unpleasant retching The passage of the tube is completely resisted in the unconscious or non-cooperative patient

To obviate these difficulties various modifications of the original model have been devised, whereby a degree of rigidity is provided the tube and its passage thereby facilitated The one described, shown in the accompanying diagram, has been tried and its usefulness proved

The tip, E, is essentially the Rehfuss "olive," but has been made somewhat longer and narrower than this Projecting into it from below is a hollow screw, F which allows a brass wire, D, 1 mm in diameter, to pass into it The wire is contained within the lumen of the rubber tube, C, at the proximal end of which is a small brass attachment, A, through which the wire passes and which possesses a set-screw, B, by which the wire may be secured

Before inserting the wire a few drops of a liquid lubricant (e g, lubafax, Burroughs and Wellcome) should be instilled into the tube by means of a medicine-dropper This allows easy insertion and withdrawal of the stylette The end of the wire is directed into the cavity of the screw in the tip of the stomach-tube the rubber is stretched slightly over the wire, and the set-screw tightened The wire is thus fixed in position and the instrument can be conducted into the œsophagus When the lower end reaches the stomach the metal attachment is removed and the stylette withdrawn

UNUSUAL CASES OF POLIOMYELO-ENCEPHALITIS

BY W. A F. COLLIS, M B CAMB, M R C P LOND,
LATE HOUSE PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

THE following four cases seem worth recording because of their unusual symptoms Similar instances are rare in the literature, though they occur during epidemics of poliomyelitis.

CASE 1 —A boy, aged 21 months, was admitted to hospital with a history of vomiting, convulsions, and loss of sight for the previous week

On examination he was found to be quite blind He had an internal strabismus and a constant upward and downward slow movement of the eyelids and eyeballs, too slow to be called nystagmus There was rigidity of the back and neck and some head retraction The reflexes were normal and there was no paralysis of the muscles The optic discs were normal The temperature was 104 6° F and the pulse rapid The cerebro-spinal fluid was under high pressure but was otherwise normal

The acute symptoms passed off in a few days and the sight gradually returned Recovery was associated with much mental irritability At the end of two months the child was discharged still weak in his legs but otherwise normal The mother reported, two months after discharge, that the boy's temperament was changed since the illness Previously he had been a quiet boy but now he was irritable and subject to violent screaming attacks at any time of the day or night.

CASE 2 —A girl, aged 20 months, was admitted to hospital with a history of vomiting and stiffness of the back and neck for two days

On examination she was flushed and apparently unconscious of her surroundings The eyes were half open and the pupils dilated She seemed unable to cry even when disturbed The temperature was 101 6° F. The knee-jerk was absent on the left side and the left leg was weaker than the right, but there was no definite paralysis or pain in the limbs The urine contained a faint trace of albumin The optic discs were normal The cerebro-spinal fluid was under pressure but otherwise normal

For about a fortnight the child ran an irregular fever, which gradually settled down The stiffness of the back and neck wore off, but it was four weeks before the girl could sit up During the period of recovery she became very irritable She was eventually discharged apparently normal in every way

CASE 3 —The patient was a boy aged three and a half years For five days before admission he had been unable to walk and had been irritable, complaining of pains in the back and limbs On admission he was very fretful and complained of headache, pains in the limbs, and much stiffness of the back and neck The temperature was 99 6° The knee-jerks were absent and Kernig's sign was present The arm reflexes were with difficulty obtained The optic discs were normal The cerebro-spinal fluid was under considerable pressure and contained 0 3 per cent albumin Four days later the child was unable to raise the left arm owing to paresis of the left deltoid muscle

He remained in hospital for about six weeks and steadily improved The weakness of the deltoid slowly passed off but he was left with an intention tremor, most marked in the hands, closely resembling that of paralysis agitans He also became very emotional and remained so until discharge

CASE 4 —A girl, aged 3 years and 8 months, was admitted to hospital complaining of lethargy, almost amounting to coma, associated with marked stiffness of the back and head retraction Three days previously there had been a sudden onset with temperature of 101°, pains in the limbs, and lethargy.

On examination she was stiff in the back and cried when touched Kernig's sign was present The optic discs were normal and the knee-jerks were obtained After admission the temperature fell almost at once and she rapidly improved, being discharged as normal three weeks later

These cases have been called poliomyelo-encephalitis although, if F E. Batten's classification[1] is followed they should be described as poliomyelitis of the midbrain and meningitic types In none of them, however, were the symptoms confined to those of one type Case 1 is the best example of a definite type as most of the symptoms can be located in the midbrain—e g, the blindness and eye movements In Case 3 the subsequent tremor was the only symptom of midbrain lesion All the cases showed stiffness of the back and other meningitic symptoms, and several showed by their subsequent mental deterioration that the higher centres had been attacked as well

---

[1] Lumleian Lectures, vide THE LANCET, 1916, i, 809

All four cases were admitted acutely ill, two of them being unconscious This is unusual in poliomyelitis where the initial illness is often mild, sudden, and of short duration The diagnosis was difficult and had to be made from meningitis and encephalitis lethargica Examination of the cerebro-spinal fluid excluded the former To exclude the latter was more difficult as encephalitis lethargica in its onset may present varying manifestations from slight headache to complete coma This difficulty arose particularly in the first case, but the general aspect was that of meningeal irritation associated with certain midbrain lesions such as blindness, which is almost unknown as an early symptom of encephalitis lethargica

The outlook in this type of case is good, judging from the above instances, though the acuteness of the onset and the possibility of subsequent mental defects should make the prognosis very guarded The treatment is largely symptomatic Lumbar puncture is useful in relieving pain and stiffness of the back This is rational as the cerebro spinal fluid always appears to be under considerable pressure

Such cases as those described are not common, but should be recognised as varieties of poliomyelitis I should like to thank the medical staff of the Hospital for Sick Children for allowing me to publish them.

A CASE OF ACUTE INFECTIVE OSTEOMYELITIS

TREATED BY CONSERVATIVE METHODS

By Herbert H Brown, O.B E., M D Lond, F R C S Eng,

CONSULTING SURGEON TO EAST SUFFOLK HOSPITAL

In some cases of acute osteomyelitis of a long bone the whole of the periosteum covering the diaphysis is separated by suppuration, accompanied by purulent infection of the bone-marrow In such cases treatment by the usual surgical methods is generally followed by necrosis of the major part, if not the whole, of the diaphysis, a large sequestrum is formed, surrounded by an involucrum of rough and irregular new bone, and this has to be removed by a second operation after a somewhat prolonged period of suppuration The final result is generally a useful but somewhat unsightly and clumsy-looking limb, the shaft of the bone being thickened and irregular

It appeared to me that it might be possible to prevent necrosis of the diaphysis, with the subsequent formation of new bone and the resulting thickening and deformity, by a thorough disinfection of the bone, the object being to allow the original diaphysis to remain and function I attempted this five years ago with a very considerable measure of success

A boy, six years old, was admitted to the East Suffolk Hospital in June, 1921, on a Wednesday, He had fallen on the preceding Thursday and bruised the left tibia Two days later the limb had become inflamed and very painful, and he had been kept in bed, treated with lotion, &c., for five days before his admission to hospital On admission he was very ill, temperature 105° F, pulse-rate 160, the left leg very much swollen, red, and acutely tender There was no sign of involvement of knee- or ankle-joints

Operation —A free incision was made along the whole extent of the inner surface of the shaft of the tibia The whole of the diaphysis was found to be bathed in pus, and the periosteum separated everywhere The pus was freely washed away, the surface of the bone and periosteum was thoroughly scrubbed first with gauze soaked in 1 in 20 carbolic lotion, then with methylated spirit, and finally with ether, and packed off with gauze, the shaft of the bone was then opened freely for the whole length of the medullary cavity The medulla, which was infiltrated with pus, was cleared away, and the cavity of the bone cleaned in a similar manner with carbolic lotion, spirit, and ether Slips of gauze soaked in bipp were placed between the periosteum and the bone and the cavity was also stuffed with gauze soaked in bipp

On the following day the temperature fell to normal, and all œdema, redness, and tenderness had disappeared. The gauze packing was removed after three days The diaphysis retained its vitality and no involucrum was formed around it There was, however, a little infection remaining in the cancellous tissue at the upper end of the medullary cavity, causing slight fever for several weeks, and leading eventually to the separation of a small sequestrum about three-quarters of an inch in length and about a quarter of an inch in its widest part

A culture of *Staphylococcus aureus* was made from the pus and a vaccine administered for several weeks

At the present time the leg appears normal externally except for the operation scar A radiograph shows that the tibia is also normal in structure, and that there is no thickening or deformity.

A CASE OF TRIGEMINAL NEURALGIA.

By J W Lloyd, M R C S Eng, L D S R C.S Edin.,

LATE HON SURGEON, LIVERPOOL DENTAL HOSPITAL

The means of treatment adopted in the following case of obstinate trigeminal neuralgia may be of interest I had occasion recently to look up my notes of it because a fellow practitioner inquired how I had secured relief for the patient.

On July 9th, 1923, the patient came to me, sent by his medical man, presenting the usual alarming and distressing symptoms of trigeminal neuralgia He was edentulous and over middle age The patient, who occupied an important commercial position, had been suffering for some months, and during the periods of attack had been completely prostrate and unable to attend to his business

I need not enumerate the symptoms as they are well known to any who have had the treatment of any such cases The attacks came regularly each evening and were started on the slightest provocation, such as a cold draught of air or the banging of a door. Treatment of similar cases with drugs and applications had never ended satisfactorily in my experience and had usually ended with injection of alcohol in the Gasserian ganglion or even with its removal As the pain started in the lower jaw, I commenced my treatment of an injection of 10 minims of a 2 per cent solution of novocaine into the right mental foramen I was far from sanguine from previous experience that any treatment would cure him, but as he gained some relief I repeated the injection on the following day and then again two days later He had so much relief from these injections that I told him not to come again until he felt any return of the pain He expressed himself as greatly benefited and said that he felt that I had got to the seat of the trouble His relief was so great that he begged me to accept double my fee

I made him a new set of dentures, thinking it possible that a redistribution of the pressure on the alveolus of the lower jaw would be desirable, his old case fitting not at all badly but pressing a little more if anything on the side where the trouble originated He assured me that his old dentures did not hurt him and that the pain was irrespective of wearing them or not When he reported that the dentures were quite comfortable he left me, and I heard no more of him until March 28th, 1927, when I was informed that he had had no recurrence

I have not found that cutting away the alveolus at the spot in which the pain originates gives more than temporary relief Any experienced person is, of course, anxious to avoid severe surgical treatment and to any practitioner who has a case of trigeminal neuralgia which is proving intractable I beg to suggest that the treatment described should be tried before injections of alcohol into, or removing, the Gasserian ganglion—a difficult and dangerous operation

Whisky at a Hospital —At the last meeting of the Galway Hospitals Committee the medical staff called attention to the fact that during the preceding month the bill for stimulants, chiefly whisky, consumed in the hospital was £25, while poultry cost only £15 "These amounts were unusually large" One "part-payment" patient consumed £2 6*s* 10*d* worth of gin in the month A member of the committee stated that up to little more than a year ago the bill for stimulants amounted to £100 a month, but that it was now usually £10 or £12 a month The matter is to be considered by the Economy Committee

Reviews and Notices of Books.

THE INFLUENCE OF MUSIC ON BEHAVIOR

By CHARLES M DISERENS, Assistant Professor of Psychology, University of Cincinnati Princeton Princeton University Press London: Humphrey Milford, Oxford University Press. 1926 Pp 224 11s 6d

THIS book must have entailed a heavy amount of work upon its author; the bibliography covers 12 pages But most of the contents are a resume of results obtained by previous observers, and the original contributions—such as the experimental studies contained in Chapter VIII—do not seem to us to have any material scientific value Everybody knows that rhythmical music has an advantageous effect upon muscular exercise—building, rowing, getting up an anchor by hand, marching, and so on—especially when these exercises are performed by a multitude of workers acting together, for the rhythm keeps the individuals together and helps them individually and collectively Everyone knows that troops march more easily and with less fatigue if they are accompanied by a band or if the men themselves sing a marching song adapted to the rhythm of the footsteps Anyone should march well to the magnificent folk tune called High Germany which is in common time, but it would be difficult if not impossible to march to a curious movement however beautiful—say, a movement in 5/4 time such as appears in Tchaikowski's Fifth Symphony.

Prof Diserens has made a number of elaborate experiments upon college pupils as to fatigue and endurance, accuracy of movement, speed of movement, effect of music on speed, size, form and character of handwriting, together with a study of the effect of single chords on the same element of handwriting, and also the effect of music on voluntary and involuntary reactions The music consisted of records played upon an Edison phonograph and the items played seem to have been mostly of a trivial character, he notes that the majority of a class of 150 students of psychology declared depressive a song called "I'll take you home again, Kathleen" The experiments suggested that music accelerated respiration, a result which can hardly have been expected Surely the tendency, at any rate if good music is in question, is towards a slowing of the respirations, and this fact may be noted by watching the respirations of a neighbour during a performance One of the subjects upon whom the experiments were made had a normal respiratory rate of only 8 3 per minute, while three others had rates of 19 and upwards respectively, so that uniform results could not have been anticipated

Prof Diserens's ideas of what constitutes music are wide In the research to show how musical stimuli affect handwriting the "music" was the following "the chord C E G D was sounded as low on the scale as possible, after five minutes the same chord was repeated as high on the scale as possible; a piano was used to produce the chord which was sounded repeatedly during the writing" We learn that the results of the experiment were almost entirely negative, but why such a discord as a tonic major ninth should have been selected we do not understand

As a collection of results observed and recorded by many workers in various fields the book is interesting, and we thank the author for the story of the lobster—"a lady's pet in Paris, said to be so fond of music that it was always drawn to the piano whenever its mistress played" If Lewis Carroll had only known this we might have had *another* verse to the immortal lobster song, thus —

"'Tis the voice of the lobster
I hear him complain,
You have played it all wrong
You must play it again."

THOUGHT AND THE BRAIN

By HENRI PIÉRON, Professor at the Collège de France Translated by C K. OGDEN, Editor of *Psyche* London Kegan Paul, Trench, Trubner and Co, Ltd 1927. Pp 262 12s

IN his preface the author enunciates with approval an aim of science as "the correlation of psychological facts with physiological mechanisms, neglecting the subjective aspect of consciousness" A reader who regards thought as essentially a subjective process associated with consciousness will be puzzled by this limited definition in a book entitled "Thought and the Brain" The work is devoted almost entirely to a full and well-documented description and discussion of the physiology and pathology of the central nervous system, especially in regard to cerebral localisation as revealed by disease or injury, and to this extent has an unquestionable value But the writer, while setting out to explain mind in terms of neurology, leaps from the known to the unknown in most disconcerting fashion In the midst of a chapter on localised lesions of areas serving the verbal function he refers (p 180) to an aphasic war patient with amnesia who could name an object and yet was unable to repeat its name when asked This hysterical prank is seriously attributed to a "functional injury" debarring the mechanism of evocation by associated paths, and the author discusses the fantasy as if it were an anatomical observation A similar pitfall for the reader is found on page 70, where, after describing the spinal innervation of the pre-axial and post-axial halves of each limb, Mr Piéron gives a reference to a case, described in 1894, in which there was a transfer of localisation from one half of the limb to the other; he gives no hint that in the original account was described a host of hysterical symptoms that suggest strongly in the light of Babinski's teaching that the altered sensation was a hysterical phenomenon induced by suggestion If the author wishes to maintain that hysterical symptoms are due to "functional injury" he owes it to his readers both to define the term and to let them know what they are reading about. Amongst "data of affective pathology" we read that ". . in most cases of insanity . essentially there is only a disturbance of the tendencies, an injury to the affective area . " and this declaration is so closely associated with pathological observations that the reader may again be unwittingly involved in metaphysics The author is unkind to the behaviourists, who take for their motto "Give me a nerve and a muscle and I will make you a mind," but the addition of cerebral structures to the recipe scarcely alters the philosophical position

As a summary of work on localisation, including that of Head on aphasia and of Gordon Holmes on visual centres, the book should be welcome to neurologists, but to the clinical psychologist it will bring disappointment

NERVES, MASTER SYSTEM OF THE BODY

By DAVID FRASER-HARRIS, M D, D Sc, F R S E London Faber and Gwyer, The Modern Health Books 1927 Pp 222 3s 6d

IT is a truism, as the introduction states, that people speak of their "nerves" without having the faintest idea of what the nervous system is, though we might also have been told that they talk similarly of stomach, heart, kidneys, with identical ignorance The author feels it worth while to replace such ignorance by a little knowledge, evidently not believing that bliss is preferable. Accordingly, the reader is introduced, in as simple language as circumstances permit, to the mysteries of neural conductivity, reflex action, cerebral function, decerebration, physical bases of consciousness, and so forth, in an interesting enough fashion, nor is there any pause to consider whether all this can be comprehended of the multitude, although the student of medicine knows well how long his art is and how many years are requisite for the accumulation of theoretical knowledge Short chapters on nervousness and the maintenance of neural health conclude the book. Incidentally, we are told that the health of the nervous system is made or marred in the first seven years of life, and that children of the nervous type ought not to be taught to read till they are about eight years old We find ourselves wondering whether attention to these dogmatisms will result in the disappearance of nervousness in the coming generation, or whether it is possible their importance is overrated. Dr Fraser-Harris has endeavoured to lighten the task set the lay reader by the introduction of apt verbal illustrations and by a few diagrams

Neurology and Psychiatry

Precis de Semeiologie Neuro-psychiatrique à l'Usage des Praticiens By Dr. A Rouquier, Professeur ágregé du Val-de-Grâce Paris · Gaston Doin et Cie 1927. With illustrations Pp 272 Fr 32

The twin sciences, neurology and psychiatry, cover between them so large a field of medical knowledge that any effort to present a compendium embracing both is faced with obvious difficulties at the outset Dr Rouquier's attempt is to be judged on its merits. Some 200 pages are devoted to the semiology of motor and sensory systems (and it is surprising how much of neurology can be comprised under these simple headings), and some 70 to psychiatric syndromes, included under the equally simple titles of constitutional psychopathic states, acute mental disorders, and chronic mental disorders Various of the author's descriptions are sketchy and consequently rather uninforming, others we consider are almost misconceived For example, to group the forms of torticollis under diseases of the basal ganglia indicates failure to appreciate the diametrically differing pathogeneses of the clinical varieties of that syndrome Thomsen's disease and writers cramp, are both, it is hinted, possibly of basal ganglionic origin—in fact, Dr Rouquier does not hesitate to give the overworked corpus striatum the responsibility for a number of dissimilar motor disorders whose objective pathology still escapes us The sections on psychiatry follow the teaching of the French school and offer the reader a somewhat one-sided presentation

The Modern Mental Hospital

By Robert Hunter Steen, M D, F R C P Lond, late Emeritus Professor of Psychological Medicine, King's College, London, and late Medical Superintendent of the City of London Mental Hospital, Dartford London. Methuen and Co, Ltd 1926 Pp 115 6*s*.

Dr Robert Hunter Steen died in July of last year at the early age of 56, after 20 years' service as medical superintendent of the City of London Mental Hospital and a professional lifetime devoted to the mentally afflicted. His outstanding quality was a rare genius for friendship, which he used to explore the minds of those whose chief trial is the lack of friends, and to discover their needs and the methods by which to fill them He succeeded as no one who relies chiefly on his intellectual gifts can succeed in this class of work, and his mastery of the psychology of the border-line case, that most difficult of all the problems of psychiatry, was admitted generally to be without equal A few months before he died he commenced a book in which his object was threefold First, he desired to strengthen true brotherhood between those who could hold their own in the world and those whose minds were unequal to the struggle, between which classes it is now recognised that no line can be drawn whatever except the fortuitous one of the hospital boundary Secondly, he desired to tell the public the intimate facts of the life of patients in mental hospitals, their surroundings, their treatment, and their prospects Thirdly, he desired to bear witness to the magnificent qualities possessed by mental nurses, a profession about which few people unacquainted with mental hospitals know much Although the book was cut short by his last illness, he has amply succeeded in his aims His first chapters describe a walk round the hospital with some friends to whom he is showing the sights the workrooms full of contented, busy and normal looking patients, the bright theatre and dining-room, the up-to-date laundry, the well-stocked farm He then talks of the patients themselves, of the difficulties of certification, and the simplicity of release, of the excellence of the voluntary system He writes clearly and well about the principles of treatment, but is obviously at his happiest when describing the parties, outings, and entertainments of which he was such a fertile inventor, and the patients' delight in them His appreciation of the nursing profession is probably the best thing in the book "I have seen them kicked, pummeled, their faces scratched, handfuls of their hair plucked out by the roots, their dresses rent from their backs, their caps and aprons torn to tatters, and yet I have never seen any loss of temper on their part From their none too extensive stocks I have known them give presents of money or articles of jewellery or wearing apparel to some overjoyed patient. When off duty they have taken patients at their own charges to do some shopping, or to a tea-shop, cinema, concert, or theatre Is it surprising, then, that we who know all these things, when we see aspersions printed about our nurses, are indignant?"

Few writers have ever explained the mental hospital to laymen, and certainly none has ever done it better At a time when the prevention and treatment of mental disease is becoming a more and more urgent problem, the value of a book like this cannot be over-estimated.

Emergency Surgery.

Dringliche Operationen Second edition By Prof. D Alexander Tietze, of Breslau Stuttgart F. Enke 1927. Pp 872. M 33

The bulk of this text-book of emergency surgery is written by Prof Tietze, but other surgeons have contributed chapters as follows anæsthesia, K. Scheyer, infusion and transfusion, Rudolf Reichle, abscess of the brain and meningitis, Hugo Hauke, ophthalmic surgery, George Lenz, nasal surgery, Max Goerke; kidney function estimation and some other urinary work, Willi Hirt, gynæcology, Robert Asch, lumbar puncture, Konrad Tietze The result is a large, carefully compiled treatise on urgent operations, including some operations which can scarcely be designated as urgent The student will find good accounts of any branch of surgery he likes to turn up, whilst the experienced surgeon will appreciate the documented reviews of such subjects as gangrene and septic joints, which are not as a rule presented succinctly in text-books of surgery Useful hints are included as to technique and methods with which the English surgeon is not familiar, for instance, the passage of a stomach-tube with an inflatable ball, which blocks the cardia before administering a general anæsthetic in intestinal obstruction All the sections are not equally good, but the book can be recommended as a sound and reliable guide to emergency surgery

The Conquest of Disease

By Thurman B Rice, A M, M D New York The Macmillan Co 1927 Pp 263. 20*s*

The large title of this book is explained in the preface by the three purposes which the author has had before him, and these, in abbreviated form, are as follows · To set forth the most recent scientific information so that transmissible diseases may be controlled or eradicated, to make the subject interesting to the general reader, and to emphasise the great advances made by science So many books, the author admits, have been written upon this and related subjects, that he has felt considerable reluctance in presenting another, and while candour suggests that there is not much in this presentation of well-known facts that will enlighten men of science, reference to the author's second object may be held to excuse the banalities Dr Rice has certainly been able to tell the story of many of the most important transmissible diseases in a form that will be intelligible to the public, and one, moreover, which should help them to recognise the grounds on which the various scientific means are adopted for their control. The book is readable throughout, and admirably printed; it should have a large circulation and be useful to readers of all sorts, given a good standard of general education

The Human Body

By TREVOR HEATON, M D London Chatto and Windus 1927 Pp 250 7s 6d

THIS book is one of the Simple Guide Series, where the various volumes have the common object to arouse interest in subjects of vital importance which, when treated scientifically, are hedged about as a rule with technicalities forming insurmountable obstacles for the general reader Dr Trevor Heaton has written here an excellent survey of the principles of anatomy and physiology and, assisted by clearness of diction, a well-planned synopsis, and many pertinent illustrations, has been able to tell a long and complicated story with remarkable brevity while maintaining interest throughout It is a tribute to the balance of the book that we cannot point to any one particular chapter as being fuller or less adequate than another, and an educated reader should be able by careful perusal to arrive at a very just view of the fundamentals of human life. One of the closing chapters, which deals with such tremendous topics, among others, as "biology and the future," "racial degeneration," "prevention and cure," and "man and the universe," seems condemned by its contents to be a mass of generalities, more or less assimilated and correlated, it is, as a matter of fact, a perfectly coherent essay in which the philosophy of medicine, never alluded to as such, informs every page.

Punishment and Personality

By HAROLD BEGBIE London Mills and Boon, Ltd 1927 Pp. 126 5s

THIS sketch of modern English prisons, the result of a tour of the penal institutions made at the instance of the *Daily Mail*, contains a great deal of interesting information sanely put; a real sympathy for the prisoners is never made doubtful by any sentimentality, and the character sketches of the inmates and their guardians, from the governor downward, are drawn with a thoroughly observant pen In the last chapter, in which the personality of the criminal is analysed, the author writes ambitiously, but this section of the book, which might easily have run off into clap-trap psychology or misplaced pathos, is a well-balanced essay written in accordance with the author's own warning to his readers that they should regard the State-inflicted punishment for law-breaking not as an attempt towards either a medical cure or spiritual discipline The result of his visits has led him to the opinion that our prison system, though in many ways praiseworthy, has yet far to go, and with this view most medical men will be in accord, and especially those associated with the Prison Service

Edmund Burke

By BERTRAM NEWMAN London: G Bell and Sons, Ltd 1927 Pp 348 8s 6d

Mr Newman has written an admirable biography and one that wanted writing Burke was amongst the greatest statesmen at the end of the eighteenth century when persons of pronounced genius and persons of equivalent imbecility conducted our State affairs We were engaged in international struggles of the most urgent and far-reaching sort, and in this country, leaders, notably Burke, were absorbed in vast political considerations, yet it is a singular comment on the time that a man of such learning, wide sympathies, and profound eloquence—our greatest political philosopher—seems never to have taken any active part in legislation for the amelioration of the social and sanitary conditions whose horrors he so constantly deplored The connexion, for example, between the Gordon riots, despite their religious surface, and the bestial circumstances in which many of the rioters lived seems to have occurred to no one in authority, and to have been voiced only by philanthropic private individuals There seems to be no authentic account of Burke's illness, which ended his life when he was 66, a fairly good age 130 years ago, but none the less an untimely one when unaccounted for by any life-history We know that he was so severely ill for over a year, as to be unable to attend to his literary work, but in the "Dictionary of National Biography" it is said that his disease "was found after death to have been internal abscesses"

Inorganic Plant Poisons and Stimulants

Second edition By WINIFRED E BRENCHLEY, D Sc, F L S, Rothamsted Experimental Station Cambridge: At the University Press 1927. Pp 134 10s 6d

THE significance to the welfare of the animal organism of traces of certain food constituents is paralleled in plants, the presence or absence of traces of inorganic salts may have a profound influence upon growth and development Since the publication of Miss Brenchley's book on this subject in 1914 a good deal of fresh evidence has been accumulated with regard to the significance of the elements boron and manganese As to the former, it appears that though toxic in higher concentrations, a small quantity of the element is in some leguminous plants—especially beans—as essential for healthy development as any of the more abundant elements generally recognised as nutritive in function while peas, curiously enough, grow to maturity and ripen viable seeds in the entire absence of boron As to manganese, small quantities appear to cause a very general stimulation of growth, but it is not yet so clearly established that manganese is essential to the life of the plant The book contains a bibliography which may be profitably consulted by those in search of first-hand information

Diseases of Animals in Relation to Man.

By THOMAS W M CAMERON, M A, B Sc, Ph D M R C V S, London School of Hygiene and Tropical Medicine London Faber and Gwyer, Ltd 1926 Pp 222 3s 6d

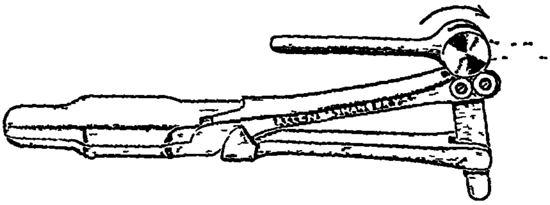
THIS book is an addition to the series of The Modern Health Books edited by Prof D Fraser Harris, who states in the introduction that the series is designed to bring within reach of everyone the latest expert opinions on the chief problems of health He adds with regard to the present volume that "there has not hitherto been written a book precisely similar to this one—a concise discussion of those morbid conditions which are common to men and animals, and on the understanding and control of which so very much of our comfort, health, and prosperity as a nation depends" The author has certainly succeeded in presenting a large amount of valuable information on technical subjects in a form that can be readily understood by the lay reader, and the book should appeal to a wide public, including the medical and veterinary professions

The introduction is taken up with a brief discussion of the general processes of infection and resistance. Tuberculosis in animals and the problems of animal tuberculosis and human health is given a prominent place Other infectious diseases such as anthrax, glanders, rabies, small-pox and cow-pox, foot-and-mouth disease, and diseases of pigs are discussed. An interesting chapter is devoted to animal parasites and fungi Milk in relation to human health is the subject of one of the longer chapters Diseases of birds are discussed separately, as is also meat and meat poisoning Brief mention is made of numerous diseases which are chiefly confined either to man or to animals, and the wide range of the subject matter makes the book a useful source of information, quite apart from its value as a treatise on public health

New Inventions.

ABDOMINAL CRUSHING CLAMPS

IN order to obtain the power required for the abdominal crushing clamp, and especially for that introduced by Mr Ernest Miles, it occurred to me that the use of an eccentrically pivoted disc might prove convenient. The illustration explains the arrangement used The handles of the forceps have slots cut in the terminal portion for the attachment of the pressure device Across one of these a strong pin passes, the other slot is open, but to the outer side of the handle at this point friction rollers are attached, one pair at each side The pressure device consists of a flat bar, slotted near one end to receive the pin in the forceps handle, while at the other end it carries the pivot of the eccentrically mounted disc, which is itself slotted to receive the bar and is provided with a handle for the application of power In use the forceps are applied in the usual way, and after compression by the hand the slotted end of the flat bar is fixed on to the pin in the forceps handle and the eccentric disc pushed on to the friction rollers with the handle of the disc pointing away from the blades of the forceps (position of minimum pressure) where it automatically fixes itself Full compression is then obtained by forcing the lever forwards—i e, toward the blades of the forceps



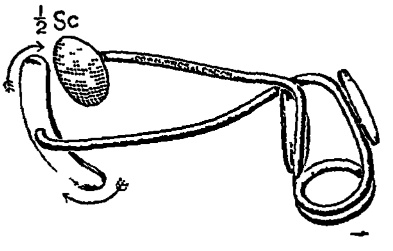
The instrument has been made according to my suggestions by Messrs Allen and Hanburys, Ltd

LAURENCE C PANTING, M D Oxf, F.R C S Eng

(1) A TONSIL COMPRESSOR, (2) A SEPTUM NEEDLE

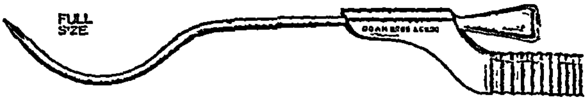
THE *tonsil compressor* (Fig 1) is a light clamp constructed on the principle of the cross-action spring It is self retaining, and no ratchet is required. The instrument is intended for use *during* the operation of tonsillectomy, and not for the arrest of severe hæmorrhage after operation It is not cumbered with any clip for the attachment of a swab. After removal of a tonsil a small swab is placed in the tonsillar fossa by means of a long dissection forceps, and the clamp then applied above this As the proximal part is at right angles, approximately, to the "business end," the clamp can be left *in situ* while the second tonsil is removed, and does not interfere in any way with the use of the guillotine or dissection instruments The second fossa can then be compressed by another clamp, and adenoids removed without any interference and in a field free from bleeding

FIG 1.



A Septum Needle—The use of a hollow needle for intranasal suture, most frequently employed at the end of submucous resection of the septum, is by far the easiest method in the limited space available; and, owing to difficulty in finding a suitable hollow needle for the purpose, I have devised the needle here illustrated (Fig 2) The proximal end is smoothly funnel shaped, and the distal end is bevelled towards the inside of the curve, the length and depth of the curve have been adopted after repeated trials to find the most suitable While retaining a certain degree of "spring," the needle is firmly mounted in a short handle The calibre is such as to admit horsehair, No 000 catgut, or ophthalmic silkworm-gut In use, the needle is threaded up to the point, and, after the needle has been passed through the edges to be sutured the suture is pushed on until it can be grasped by a forceps; the needle is then withdrawn, and the suture is left in place ready for tying Not only can the edges of the incision be readily sutured in this way, but small tears in the septal flaps, even far back in the nose, can be repaired, the knot being slipped back by holding one end of the suture in a Tilley's forceps

FIG. 2



Both instruments are made in stainless steel by Messrs Down Bros, St. Thomas's-street, S E 1

H. ROSS SOUPER, M D Aberd

Reports and Analytical Records.

FRIEDRICHSHALL NATURAL MINERAL WATER.

PROPRIETORS C OPPEL AND Co, FRIEDRICHSHALL, SAXE MEININGEN, GERMANY
AGENTS FOR GREAT BRITAIN AND IRELAND INGRAM AND ROYLE, LTD, 45, BELVEDERE ROAD, LONDON, S E 1

THIS well-known water can be used as an ordinary aperient, for congestion and fatty degeneration of various organs, as a preventive against uric acid, gravel and stone in the bladder, and in the treatment of gout The water is bright in appearance, odourless, and has a pronounced bitter saline flavour When analysed the following results were obtained —

	Parts per 100,000		Parts per 100,000
Total solids after ignition	2700	Iron (Fe_2O_3) } Alumina (Al_2O_3) }	8 0
Sodium (Na)	572 6	Chlorine (Cl)	958 5
Magnesium (Mg)	251 8	Sulphates (SO_4)	920 0
Calcium (Ca)	16 0		2730·0
Silica (SiO_2)	4 0		

Specific gravity—1023 0

It is customary in setting out the analysis of a water to show the acids and bases combined as salts so as to indicate the manner in which they exist in solution. Among other possible combinations this water may have the following composition —

	Parts per 100,000		Parts per 100,000
Soldium chloride	1023	Oxides of iron and alumina	8
Sodium sulphate	523	Calcium carbonate	23
Magnesium chloride	436	Calcium chloride	20
Magnesium sulphate	708		2745
Silica	4		

The water was free from organic impurities

VICTORIA HOSPITAL FOR SICK CHILDREN—Mrs Alexander Campbell has opened an artificial light department at this hospital in Tite street, Chelsea The cases suffering from tuberculous glands are doing well, and Dr Murray Levick stated that the results obtained justified the conclusion that children living in their own homes and attending the hospital for a prolonged course of treatment three times a week progressed as well as those who were sent to Alpine institutions

THE LANCET.

LONDON: SATURDAY, APRIL 30. 1927.

TRIBUTION OF GOITRE IN ENGLAND AND WALES.

countries which enforce military conscription geographical distribution of goitre can be deduced the physical condition of recruits, but in England eliable statistics were available until the recent rt of school medical officers throughout the try on the incidence of goitre among schoolren during the year 1924–25 The investigation nade at the request of the Board of Education, vas not limited to an enumeration of the children showed enlargement of the thyroid. Much eral research was undertaken, and this made it nce again that simple goitre is the outward and sign of a general physiological imbalance ENNETH FRASER, assistant medical officer of for Cumberland, regards goitre as a danger-indicating a grave departure from the normal g of the body as a whole. This departure is ssociated with disease, and Dr. E H. MILLIGAN. sop, points out that in goitrous children there increased incidence of ear, nose, and throat ns, and also of rheumatism, Dr. DUNSTAN R, of Swindon, finds that myopia is twice as n in them as in normal children, whilst other rs, as is well known, attribute a variety of s to thyroid inefficiency Were simple goitre ely to iodine deficiency these far-reaching lic changes would be harder to explain than ieut -Colonel R. MCCARRISON's latest experi-work seems to suggest (see p 916), goitre is ted with an ill-regulated diet short of certain ry factors

apart from concurrent abnormal conditions body which may be related to goitre, it is by ns clear what association there is between toxic ophthalmic goitres and those of the simple With a view to eliciting some relationship M H CAMPBELL recently made a detailed of the school medical officers' reports in order pare the distribution of simple goitre with the ation of deaths from exophthalmic goitre as inable from the reports of the Registrar-l. An initial difficulty was to find a definition tre comprehensive enough to make the results medical inspectors comparable For this e they were divided—though the classification uttedly imperfect—into those in whom the l was so much enlarged that the increase in the the neck was noticed on casual inspection ut measurement or palpation), and those in it was not thus enlarged Previous investiga-ad shown that the incidence of goitre in school-n is greatest at the leaving age, and in his Dr CAMPBELL therefore included only children en 13 and 14 years of age. He found that dual variations in the reports were very great, eighbouring towns or areas where the conditions similar showed such differences that he decided arrange them Small areas were combined in larger ones, and Dr CAMPBELL believes that certain general conclusions can be drawn from the results The figures for county areas were regarded as being most likely to give the geographical information required, and were therefore considered in detail.
